AHRQ Publication No. 18-05242-EF-1
June 2018
This report is based on research conducted by the Kaiser Permanente Research Affiliates Evidence-based Practice Center (EPC) under contract to the Agency for Healthcare Research and Quality (AHRQ), Rockville, MD (Contract No. HHSA-290-2015-000017-I-EPC5, Task Order No. 2). The findings and conclusions in this document are those of the authors, who are responsible for its contents, and do not necessarily represent the views of AHRQ. Therefore, no statement in this report should be construed as an official position of AHRQ or of the U.S. Department of Health and Human Services.

The information in this report is intended to help health care decisionmakers—patients and clinicians, health system leaders, and policymakers, among others—make well-informed decisions and thereby improve the quality of health care services. This report is not intended to be a substitute for the application of clinical judgment. Anyone who makes decisions concerning the provision of clinical care should consider this report in the same way as any medical reference and in conjunction with all other pertinent information (i.e., in the context of available resources and circumstances presented by individual patients).

The final report may be used, in whole or in part, as the basis for development of clinical practice guidelines and other quality enhancement tools, or as a basis for reimbursement and coverage policies. AHRQ or U.S. Department of Health and Human Services endorsement of such derivative products may not be stated or implied.

Acknowledgments

The authors gratefully acknowledge the following individuals for their contributions to this project: Ernest Sullivent, MD, MPH, and Amanda Borsky, DrPH, MPP, at AHRQ; current and former members of the U.S. Preventive Services Task Force who contributed to topic deliberations; Richard Saitz, MD, MPH, at Boston University Schools of Medicine and Public, for his content expertise and review of the draft report; Meghan Soulsby Weyrich, MPH, at the University of California, Davis Center for Healthcare Policy and Research, for her assistance in data abstraction; and Smyth Lai, MLS, and Katherine Essick, BS, at the Kaiser Permanente Center for Health Research for technical and editorial assistance.
Structured Abstract

**Importance**: Unhealthy alcohol use is common and increasing in adults and is the most common cause of premature mortality in the United States.

**Objective**: To systematically review the benefits and harms of screening and nonpharmacologic interventions to reduce unhealthy alcohol use to inform the U.S. Preventive Services Task Force.

**Data Sources**: MEDLINE, PubMED, PsycINFO, Cochrane Central Register of Controlled Trials through October 12, 2017; references of relevant publications, government Web sites.

**Study Selection**: English-language trials of benefits and harms of screening in health care settings or other comparable populations and nonpharmacologic interventions to reduce unhealthy alcohol use in screen-detected people who report unhealthy alcohol use, and test accuracy studies of selected screening tools to detect unhealthy alcohol use.

**Data Extraction and Synthesis**: Two investigators independently reviewed abstracts and full-text articles, then we extracted data from fair- and good-quality trials, based on predetermined criteria. Random-effects meta-analysis was used to estimate benefits of the interventions.

**Main Outcomes and Measures**: The primary drinking outcomes were drinks per week, exceeding recommended alcohol use limits, heavy use episodes, and, for pregnant women, abstinence. Other outcomes included mortality; quality of life and consequences of alcohol use; injuries, accidents, and acute health-care utilization; family, social, and academic functioning; and legal outcomes.

**Results**: We included 108 studies (n=309,534) across all key questions. We did not find any studies that examined the benefits or harms of screening programs to reduce unhealthy alcohol use. For adolescents, data supported the use of the National Institute on Alcohol Abuse and Alcoholism (NIAAA) Youth Screen and other similar one- or two-item screeners to detect alcohol use disorder. For adults, brief (1–3 item) screeners commonly reported sensitivity and specificity between 0.70 and 0.85, typically having better sensitivity than the full Alcohol Use Disorders Identification Test (AUDIT) for identifying the full spectrum of unhealthy use. However, the AUDIT tended to have higher specificity, particularly at the standard cutoff of ≥8. Evidence on the effects of interventions to reduce unhealthy alcohol use in adolescents was limited to two trials; both found mixed results for reduced alcohol use and did not report health or related outcomes. In adults, interventions reduced drinks/week (weight mean difference [WMD]=−1.82 [95% CI, −2.42 to −1.22]), the proportion exceeding recommended drinking limits (odds ratio [OR]=0.60 [95% CI, 0.53 to 0.67]), and the proportion reporting a heavy use episode (OR=0.62 [95% CI, 0.55 to 0.71]), and increased the proportion of pregnant women reporting abstinence (OR=1.92 [95% CI, 1.19 to 3.09]) after 6 to 12 months. Analyses limited to trials conducted in primary care settings and the United States suggested that effects in these most applicable trials were comparable or larger than the overall effect (e.g., for trials in primary care settings, WMD=−2.82 [95% CI, −3.87 to −1.76]). Benefits remained through 24 months or beyond in four of seven trials with longer-term outcomes. Heterogeneity was high and effect size was associated with a number of study characteristics such as setting, target age of the population,
publication year, study size, and average baseline-use levels, but not clearly associated with any intervention characteristics. Data on effectiveness in important subgroups were very limited, but analyses by gender, the most commonly-reported subgroup analysis, did not indicate differences in effectiveness of the interventions. Health outcomes were sparsely reported and, with some exceptions, generally did not demonstrate group differences in effect. We found no evidence that these interventions could be harmful.

**Conclusion:** Among adults, screening instruments are available that can effectively identify people with unhealthy alcohol use and that are feasible for use in primary care settings, and interventions in those who screen positive are associated with reductions in unhealthy alcohol use. There was no evidence that these interventions have unintended harmful effects. More evidence is needed to determine whether screening for unhealthy alcohol use is beneficial for adolescents.

Chapter 1. Introduction

Condition Definition

Unhealthy alcohol use encompasses a wide range of behaviors, from drinking above the recommended limits (i.e., risky drinking) to severe alcohol use disorder. Types of unhealthy alcohol use are listed in Table 1 and are not mutually exclusive; for example, persons with alcohol use disorders also meet criteria for harmful use. The National Institute on Alcohol Abuse and Alcoholism (NIAAA) recommends that men ages 21 to 64 years consume no more than 4 drinks per day (56 grams/day, according to the United States standard of 14 grams/drink) and no more than 14 drinks per week (196 grams/day), based on the standard drink amount of a 12-ounce beer (5% alcohol), 5 ounces of wine (12% alcohol), or 1.5 ounces of distilled spirits (40% alcohol). For women of any age and men ages 65 years and older, the recommendation is to consume no more than three drinks per day and seven drinks per week (42 grams/day or 98 grams/week). The NIAAA guide for youth ages 18 and younger suggests criteria that vary by age: for example, for 12 to 15 year-olds, any drinking in the past year is considered moderate risk and drinking on 6 or more days in the past year is considered high risk; for 18-year-olds, 12 to 51 drinking days is considered moderate risk and 52 or more days is considered high risk. A person meets Diagnostic and Statistical Manual of Mental Disorders (DSM-5) criteria for alcohol use disorder (AUD) if they experience at least two of the 11 criteria listed in Appendix A Table 1; severity of the disorder is specified (mild, moderate, severe) and based on the number of criteria met. This is a change from previous versions of the DSM, which had separate diagnoses for alcohol abuse and alcohol dependence (Appendix A Table 1). DSM-5 severity modifiers of moderate or severe correspond to alcohol dependence in earlier versions of the DSM and the International Statistical Classification of Diseases and Related Health Problems (ICD) system.

Defining unhealthy levels of drinking is complex and challenging. The primary evidence informing the established cut points comes from epidemiological evidence and studies of adults providing dose-response curves, which involve nuanced interpretation. The primary challenge in setting these limits is determining the threshold that divides “low risk” and “high risk” drinking. These interpretations rely on decisions regarding what level of harm has substantial enough magnitude to warrant caution, as well as what types of harms should be considered. As a result, there is no firm consensus worldwide regarding the definition of risky drinking, and the definition of a standard drink varies between nations.

Prevalence

Unhealthy alcohol use is relatively common and is increasing in adults. Based on the 2016 National Survey on Drug Use and Health (NSDUH), an estimated 14.6 million adults met the criteria for having AUD, representing 7.8 percent of men and 4.2 percent of women. Prevalence figures by age are shown in Table 2. Among adults ages 18 and older, 26.2 percent reported heavy use episodes (≥5 drinks on the same occasion on ≥1 day in the previous month, also referred to as binge episodes) and 6.6 percent reported engaging in heavy drinking (≥5 drinks on the same occasion on ≥5 days) in the previous month. Additionally, 9.2 percent of adolescents,
ages 12 to 17 years, reported being current alcohol users and 4.9 percent reported heavy use episodes in the previous month. Furthermore, an estimated 488,000 (2.0%) adolescents were reported to have AUD, representing 2.4 percent of females and 1.5 percent of males. Among college students (regardless of age), 57.2 percent reported any past-month alcohol use, 38.0 percent reported past-month heavy use episodes, and 10.5 percent reported past-month heavy alcohol use. Rates of AUD are lower for older adults (1.6%) as are rates of having heavy use episodes in the past month (9.7%) and past-month heavy alcohol use (2.3%).

According to the National Epidemiologic Survey on Alcohol and Related Conditions (NESARC), high-risk drinking increased by 29.9 percent between 2001-2002 and 2012-2013 among adults in the United States. Increases were particularly pronounced among women (57.9% increase), nonwhites (40.3% to 62.4% increases), and older adults (65.2% increase). Similarly, the prevalence of AUD increased from 8.5 to 12.7 percent, a 35.7 percent increase. The largest increases were seen in women (59.8% increase), blacks (55.8% increase), and adults ages 45 and older (61.9% to 75.0% increases). It is unclear why the NESARC identified substantially higher AUD prevalence than the NSDUH cited above, but the NESARC methods were almost identical across survey years, so the trend over time is likely reliable. Further, its finding of increased prevalence of unhealthy use over time is supported by similar trends seen in other large-scale national surveys, for both general and older adult populations. Interestingly, however, the NSDUH data show a declining trend in the proportion of adolescents reporting alcohol use in the previous month, and slight reductions between 2015 and 2016 on unhealthy use in adults, so it is unclear whether the rising trend has continued beyond 2012-2013. Reviewers have noted that declining gender differences in prevalence of alcohol use likely reflect changes in sociocultural environments, and that countries with rising alcohol use rates are showing smaller gender differences in rates of alcohol use, earlier onset of alcohol use, and earlier development of alcohol use disorder symptoms in younger cohorts compared with older cohorts.

Disparities exist among racial and ethnic minorities and underserved populations in terms of the prevalence of AUDs and overall drinking patterns, as well as adverse health effects and consequences related to heavy alcohol use. The recent publication analyzing NESARC data from 2012 to 2013 referenced above found that the odds of developing an AUD of any severity in the previous 12 months was significantly higher among men (AdjOR 1.9 [95% CI, 1.72 to 2.01]) versus women, and individuals living in urban cities (AdjOR 1.4 [95% CI, 1.20 to 1.55]) versus rural environments. A greater percentage of Native Americans (19.2%) reported AUDs of any severity in the previous 12 months followed by Blacks (14.4%) and Whites (14.0%), but the difference in prevalence between race/ethnicities was not found to be significant. That same trend was seen among those with family incomes less than $20,000 per year (16.2%) versus those of higher SES (12.7 to 14.0%). Drinking patterns have also been found to vary by race/ethnicity, with Hispanics (17.2%) being shown to have the highest prevalence of binge drinking, followed by Blacks (15.6%) and Whites (14.8%). Additionally, Hispanic men are reported to have a higher drink maximum in a day (7.4) compared with White (7.0) and Black (4.9) men. Although Native Americans have been shown to have higher rates of heavy and binge drinking compared with other race/ethnicities, recent evidence has been mixed.
Burden

Excessive alcohol use is one of the leading causes of premature mortality and is responsible for 1 in 10 deaths among working-age adults aged 20 to 64 years in the United States.\textsuperscript{16} From 2006 through 2010, the average annual alcohol-attributable deaths in the United States were 87,798 (27.9/100,000 population), with an estimated 2.5 million years of potential life lost.\textsuperscript{16} Overall, 44 percent of these deaths were due to chronic conditions (e.g., alcoholic liver disease) and 56 percent were due to acute conditions (e.g., motor-vehicle traffic crashes). In 2013, there were 29,001 deaths directly related to alcohol use, which does not include mortality from unintentional injuries, homicides, and other causes indirectly related to alcohol use.\textsuperscript{17} In the United States, 3.2 to 3.7 percent of cancer deaths (18,200 to 21,300 deaths) are attributed to alcohol use, including cancers of the breast, oral cavity and neck, and gastrointestinal sites,\textsuperscript{18} Men are more likely to die from alcohol-related causes than women—the age-adjusted death rate was 2.9 times higher in men than women in 2013.\textsuperscript{17} Additionally, 5.1 percent of the global burden of disease and injury in disability-adjusted life years was related to alcohol.\textsuperscript{19}

Consuming alcohol while pregnant can result in fetal alcohol spectrum disorders (FASDs), as well as additional adverse birth outcomes, making alcohol use throughout pregnancy a major preventable cause of birth defects and developmental disabilities.\textsuperscript{20} Prenatal exposure to alcohol can affect the developing brain, heart, kidney, liver, gastrointestinal tract, and endocrine systems.\textsuperscript{21} Data from the 2011 to 2013 Behavioral Risk Factor Surveillance System (BRFSS) survey showed that 1 in 10 pregnant women ages 18 to 44 years reported consuming alcohol in the previous month and 3.1 percent participated in binge drinking.\textsuperscript{20} Beyond the harmful effect of alcohol use during pregnancy, evidence shows that women who engage in unhealthy alcohol use are more susceptible to the deleterious health effects, including liver and cognitive effects, than men with unhealthy alcohol use. These effects may be mediated by the effects of alcohol on sex hormones and in alcohol pharmacokinetics’ effect on the brain.\textsuperscript{11}

College students’ health also suffers with unhealthy alcohol use. For example, an estimated 1,825 college students between the ages of 18 and 24 have died annually from alcohol-related, unintentional injuries, including motor-vehicle crashes.\textsuperscript{22, 23} Approximately 696,000 students between the ages of 18 and 24 were assaulted by another student who had been drinking, and 97,000 students between the ages of 18 and 24 report experiencing alcohol-related sexual assault or date rape.\textsuperscript{22, 24} About 1 in 4 college students report academic consequences from drinking, including missing class, falling behind in class, doing poorly on exams or papers, and receiving lower grades overall.\textsuperscript{22, 25}

In 2010, excessive alcohol use was estimated to cost the United States $249 billion, with State and Federal governments paying $100.7 billion, or just over 40 percent of these costs.\textsuperscript{26} The majority of the cost of excessive alcohol use was due to binge drinking (76.7%), while underage drinking accounted for 9.7 percent, and drinking while pregnant was 2.2 percent ($5.5 billion) of the total cost. The majority of the economic cost of excessive alcohol use is due to losses in workplace productivity (72%), followed by health care expenses (11%), law enforcement and criminal justice expenses (10%), and losses from motor vehicle crashes (5%).\textsuperscript{26} These estimates are thought to be underestimates, however, due to the fact that information on alcohol is typically underreported or unavailable. Additional costs including pain and suffering due to alcohol-
related injuries and alcohol-related morbidities are not included.

The United States national drinking guidelines are consistent with the evidence on risk levels reported in meta-analyses of observational literature. One meta-analysis found that the average daily volume (ADV) at which an increased risk of all-cause mortality is approximately 38 grams of ethanol (2.7 drinks, according to the United States standard), and appear to be lower for women than for men. In addition, the risk of liver disease and a number of cancers (primarily of the gastrointestinal tract, liver, and breast) are increased at an ADV of approximately 25 grams (1.8 drinks per day). A more detailed discussion of the epidemiology of the health effects of alcohol use is in Appendix B.

In addition to disparities in the prevalence of AUDs and drinking patterns, disparities are also found in alcohol-related social and health problems. Data from the NSDUH shows that Whites and Native Americans report the highest rates of driving under the influence in the previous year with 15.6 percent of Whites and 13.3 percent of Native Americans reporting this activity. Research has also shown that the rates of alcohol-attributed violence and intimate partner violence (IPV) varies by race/ethnicity. A study by Schafer and colleagues found that the reporting of unhealthy alcohol use increased the risk of IPV in Black couples compared with White and Hispanic couples. Alcohol use has also been found to contribute to the victimization among Native Americans, with numerous studies reporting that Native Americans are at greater risk of alcohol-related trauma (IPV, rape, and assault) when compared with other ethnic groups in the United States. Alcohol-related morbidity and mortality are also found to vary across racial and ethnic groups. Hispanics and Blacks have been shown to have a greater risk of developing liver disease compared with Whites, and Hispanic men are reported to have the highest incidence of liver cirrhosis mortality compared with other ethnicities. Further, the incidence of alcohol-related esophageal cancer and pancreatic disease are higher for Black men than White men and fetal alcohol syndrome and fetal alcohol spectrum disorders are more prevalent in Blacks and Native Americans. A review of peer-reviewed and national surveillance reports found that Native Americans experience the highest rates of alcohol-attributable motor vehicle crash mortality, suicide, and falls compared with other racial and ethnic groups.

**Risk Factors and Etiology for Alcohol Use Disorders**

Excessive use of alcohol can affect neurobiological functioning in the basal ganglia, extended amygdala, and prefrontal cortex, leading to the development of alcohol tolerance (needing larger amounts to feel “high”), diminution of pleasure from everyday human activities such as food and social interaction, increased release of neurotransmitters associated with stress when alcohol is absent from the body, and ultimately addiction. Not surprisingly, initiation of drinking at younger ages, when the brain is rapidly developing and changing, is associated with an increased risk of unhealthy alcohol use. For example, an analysis of the 2010 NSDUH data found that younger age at first use of alcohol was associated with increased likelihood of reporting a heavy use episode in the past month. Similarly, NESARC found that the odds of developing alcohol dependence are 2.3 times higher when initiation of alcohol use occurs prior to age 15, compared with initiation after age 18 (adjusted OR 2.33 [95% CI, 1.74 to 3.13]), with similar results for
alcohol abuse. Additionally, childhood maltreatment, specifically sexual abuse and/or physical abuse, increases the risk of developing alcohol use disorders. For example, a 2016 study of young adults (n=300) found that childhood physical abuse (≤18 years of age) more than doubled the odds of alcohol use disorders in young adulthood (adjusted OR 2.41 [95% CI, 1.31 to 4.45]; p<0.01).

Alcohol use disorders commonly co-occur with personality and mood disorders, although the causal relationship between them is unclear and likely variable. Parental history of an alcohol use disorder increases the risk of alcohol use disorders in their children. The Copenhagen Perinatal Cohort study (n=9,125) found that offspring of parents with an alcohol use disorder have approximately twice the odds of developing an alcohol use disorder, compared with offspring of parents without an alcohol use disorder. Another population-based cohort study (n=398,881) found that the risk for offspring of developing an alcohol use disorder increased when one or both parents had the disorder (adjusted Hazard Ratio 1.44 [95% CI, 1.29 to 1.61] and 2.29 [95% CI, 1.64 to 3.20] for persons with one and both parents with an alcohol use disorder, respectively).

A study of twins suggests that risk factors for alcohol use disorder may differ between men and women. They found that, for women, family history of alcohol use disorder, early-onset anxiety disorders, and nicotine dependence were strong risk factors of alcohol use disorders. In men, important risk factors included novelty seeking, conduct disorder, childhood sexual abuse, parental loss, neuroticism, low self-esteem, and low marital satisfaction.

**Rationale for Screening**

While persons with severe alcohol use disorder are likely to be identified through the health and social impacts of their alcohol use, those with lower levels of unhealthy alcohol use may not be easily identifiable without direct questioning. Yet unhealthy alcohol use affects a wide range of medical conditions that are commonly encountered in the primary setting, including (but not limited to) gastrointestinal, cardiopulmonary, dermatologic, reproductive, and neurological conditions. Further, alcohol interacts dangerously with many commonly used prescription and over-the-counter medications. Because of these factors, patients’ alcohol use can have a substantial impact on their treatment for and recovery from many (if not most) conditions that are addressed in primary care, and efforts to reduce unhealthy alcohol use have substantial potential to improve the health of primary care patients. If screening and counseling can reduce alcohol use to within recommended limits, such health effects could possibly be avoided.

Further, screening and intervention for lower levels of unhealthy alcohol use in adolescents and younger adults, before their neurochemistry has been affected by chronic or heavy use, offer an important opportunity to avoid progression to more serious and likely difficult-to-treat levels of use.

The 2016 United States Surgeon General report has identified screening in health care settings as an important vehicle for identifying persons with unhealthy alcohol and substance use, and primary care-based alcohol screening and counseling were among the highest-rated preventive services in terms of clinically preventable burden in a study exploring health impact and cost-
effectiveness of preventive clinical services. To further support screening and interventions in primary care settings, patients have expressed a preference for treatment in primary and collaborative care settings, rather than specialty settings.

Screening Strategies

Primary care practitioners have limited time to interact with their patients; therefore, brief or self-administered screening tests that identify the full spectrum of alcohol use are preferable to elaborate tools that occupy more clinician time. Numerous brief instruments have been developed (Appendix C); however, only a few have gained widespread use in clinical or research settings. For patients screening positive on a brief screener, followup questions are needed to confirm the presence of unhealthy use, assess the extent of unhealthy alcohol use, and help the patient and clinician determine appropriate next steps. Several clinician guides (see Table 3) have been developed that lay out next steps after the initial assessment, which may include brief counseling, followup visits with the primary care clinician, a thorough assessment by an addiction medicine or mental health specialist, referral to community and specialty services, and medication.

The previous systematic review to support the 2013 United States Preventive Services Task Force (USPSTF) recommendation identified one- or two-item screeners such as the NIAAA-recommended Single Item Alcohol Screening Questionnaire (SASQ), the Alcohol Use Disorders Identification Test (AUDIT), and the AUDIT-Consumption questions (AUDIT-C) as having the best accuracy among the instruments they examined to screen for any level of unhealthy alcohol use among adults. The SASQ asks, “How many times in the past year have you had 5 [for men]/4 [for women] or more drinks in a day?” where one or more occasions in the previous year constitutes a positive screen. The AUDIT-C includes three items covering frequency of alcohol use, typical amount, and occasions of heavy use. The full AUDIT includes these three items, plus seven questions regarding signs of alcohol dependence and common problems associated with alcohol use (e.g., being unable to stop once you start drinking, needing a drink first thing in the morning). The U.S. Department of Veterans Affairs (VA) specifically recommends annual screening with the AUDIT-C and SASQ. The Cut down, Annoyed, Guilty, Eye-opener (CAGE) screener is another developed to detect alcohol dependence rather than the full spectrum of unhealthy alcohol use, and was used for screening in multiple treatment trials included in the previous review.

Screening instruments have also been developed for special populations, including adolescents, older adults, and pregnant women. For adolescents, the NIAAA recommends two items, asking about the patient’s alcohol use and their friends’ use. The NIAAA also developed the related Brief Screener for Tobacco, Alcohol, and other Drugs (BSTAD) to use this approach to assess alcohol, tobacco, and drug use. Both the NIAAA and American Academy of Pediatrics (AAP) name the Car, Relax, Alone, Forget, Family, Friends, Trouble (CRAFFT) screener as a useful screening tool for identifying risky substance use in adolescents, which assesses riding in or driving a car while intoxicated, use of alcohol or drugs to relax, use when alone, forgetting what you’ve done while intoxicated, having friends or family suggest you cut down, and getting into trouble while using alcohol or drugs.
The Comorbidity Alcohol Risk Evaluation Tool (CARET) was developed for older adults. The CARET is a briefer version of two relatively lengthy instruments (the Alcohol-Related Problems Survey [ARPS] and the Short-ARPS [shARPS]) included in the previous review and was found to have acceptable accuracy but low feasibility for routine screening in primary care. The CARET includes items about common medications and medical conditions that could interact with alcohol to further characterize the risky nature of alcohol use in older adults.

Four instruments have been specifically developed to screen for problematic alcohol use during pregnancy: Tolerance, Worried, Eye-openers, Amnesia, Kut down (TWEAK); Tolerance-Annoyed, Cut down, Eye opener (T-ACE); Past use, Pregnancy, use by Parents and Partners (4P’s Plus); and the Normal drinker, Eye opener, Tolerance (NET). Of these, a previous review concluded that the TWEAK and T-ACE performed best for pregnant women, along with the AUDIT-C. The T-ACE is specifically mentioned in the American College of Gynecologists and Obstetricians’ (ACOG) recommendation on alcohol screening.

Finally, the World Health Organization (WHO) developed the Alcohol, Smoking and Substance Involvement Screening Test (ASSIST) screen for substance use more broadly, covering unhealthy use of drugs and smoking as well as alcohol. It has been validated in adults (age 18 and older) and shows good cross-cultural neutrality.

**Interventions for Unhealthy Alcohol Use**

For persons with unhealthy drinking behavior who do not have an alcohol use disorder, a brief intervention to increase the awareness of alcohol use and increase motivation to make behavioral changes in primary care may be sufficient, while those with AUD may need referral to more extensive treatment, possibly including medication-assisted treatment. Medications approved by the Food and Drug Administration (FDA) for the treatment of unhealthy alcohol use are intended for those diagnosed with an alcohol use disorder and are generally used after they have achieved abstinence. These medications include acamprosate, disulfiram, and naltrexone, which aim to reduce symptoms of abstinence, create a physical reaction if alcohol is consumed, or block the rewarding effects of drinking.

A number of health organizations have developed clinician guides for primary care-based interventions to reduce unhealthy alcohol use, some of which also provide implementation advice and planning documents (Table 3). Their approaches fall under the Screening, Brief Intervention, Referral, and Treatment (SBIRT) framework, and typically use the Ask, Advise, Assess, Assist, Arrange (5 A’s) mnemonic, either explicitly or implicitly. Organizations generally recommend a very brief 1- to 3-item screener, followed by more in-depth risk assessment among those who screen positive. Once unhealthy alcohol use is identified, guides typically suggest providing feedback to the patient on their alcohol use; advising the patient to reduce their alcohol use; having a discussion with the patient to understand their readiness to change and develop goals and an action plan, if the patient is willing; and arranging for followup. Guides typically incorporate motivational interviewing tools to help patients increase their readiness to change, such as open-ended questions, affirmation, reflective listening, and summaries, along with standard motivational techniques such as expressing empathy, supporting
self-efficacy, pointing out previous successes, rolling with resistance, and helping patients see the discrepancy between where they are and where they want to be. One review provides important perspective and recommendations on potential adaptations to SBIRT interventions for culturally diverse populations.\textsuperscript{59} Beyond these clinician guides, counseling interventions have been developed that include a wide range of approaches (e.g., motivational enhancement therapy, cognitive behavioral therapy, 12-step), specific strategies (e.g., action plans, drinking diaries), delivery methods (e.g., face-to-face, Web-based, individual, group-based), length of contact (e.g., brief, extended), and number of contacts (single, multiple).\textsuperscript{60} NIAAA has developed an online resource to help individuals understand treatment options, find practitioners, and recognize signs of higher-quality care for AUD. This is a comprehensive and easy-to-use tool to help patients and their families navigate the often complicated process of finding and choosing a treatment option.\textsuperscript{61}

**Current Clinical Practice in the United States**

Despite current clinical recommendations for physicians to screen patients for unhealthy alcohol use and provide brief counseling for those engaging in unhealthy drinking behaviors, not all physicians report following these recommendations in their practices. A 2016 cross-sectional survey of New York primary care physicians and nonphysician providers (n=213) found that approximately half (57\%) reported screening patients for substance use (drugs as well as alcohol).\textsuperscript{62} Further, 46 percent of respondents reported providing a brief intervention to patients who were found to meet criteria for unhealthy use and 47 percent gave a referral to treatment. In a survey of primary care residents, 60 percent reporting that they “usually” or “always” screened patients for unhealthy alcohol use; however, only 19 percent used screening instruments capable of detecting heavy use episodes.\textsuperscript{63} When compared with physicians, nonphysician providers (i.e., nurse practitioners and physician assistants) felt less comfortable talking with their patients about alcohol and drug use (p=0.004), and were less likely to perform a brief intervention (52\% vs. 32\%, p <0.0005) or refer a patient to treatment (50\% vs. 70\%, p = 0.001).\textsuperscript{62} Data from the patient perspective confirm that screening for unhealthy alcohol use is widely employed: 78 percent of patients reported that in the previous 2 years they were asked by a health care professional about their alcohol use, and 68 percent were asked how much alcohol they use, according to the BRFSS survey.\textsuperscript{64} However, only 15.7 percent of adult respondents reported having a discussion about their use of alcohol with their providers; counseling was more common among binge drinkers but still fairly low (25.4\% had ever discussed it, 13.4\% discussed it in the previous year).\textsuperscript{65} Even lower screening and counseling rates have been reported among young adults\textsuperscript{66} and women’s reproductive health clinicians.\textsuperscript{67}

Physicians report a number of common barriers to achieving higher rates of screening patients for unhealthy alcohol use. These include not having enough time to conduct a further assessment and counseling in the event of a positive screen, lack of adequate training about how to properly screen patients, not feeling confident about being able to assist patients meeting the criteria for unhealthy use, not feeling comfortable discussing alcohol use with patients, not trusting that their patients would be honest about their alcohol use, and not feeling that available treatments were effective.\textsuperscript{62, 63, 68} Clinic staff have also reported concerns that screening would interfere with the clinic flow.\textsuperscript{69}
Recommendations of Others

Recommendations and statements from other organizations about screening and treatment for unhealthy alcohol use are summarized in Appendix D. The VA, Surgeon General of the United States, NIAAA, the CDC, and the American Society of Addiction Medicine (ASAM) all agree with the 2013 USPSTF recommendation that adult patients should be routinely screened for at-risk drinking and brief counseling should be provided to patients who are determined to have unhealthy alcohol use behaviors.70-74 Additionally, the NIAAA recommends medical management for adults with alcohol dependence. The AAP recommends that pediatricians increase their capacity in substance use detection, assessment, and intervention and that they be familiar with SBIRT practices.75 Both the ACOG and the WHO recommend that all women should be screened both before pregnancy and in their first trimester of pregnancy via validated tools (e.g., TACE) and that providers should offer a brief intervention to all pregnant women using alcohol.19, 76

Previous USPSTF Recommendation

In 2013, the USPSTF recommended that clinicians screen adults age 18 years or older for alcohol misuse and provide brief behavioral counseling interventions to reduce alcohol misuse to those engaged in risky or hazardous drinking behaviors (B recommendation).60 The USPSTF concluded, however, that the evidence was insufficient to assess the balance of benefits and harms of screening and behavioral counseling interventions to reduce alcohol misuse in adolescents (I statement).
Chapter 2. Methods

Scope and Purpose

This systematic review examined the evidence for the benefits and harms of screening for unhealthy alcohol use and interventions to reduce unhealthy alcohol use in nondependent alcohol users in primary care-relevant settings (primary care, other outpatient health care settings) or in other general populations judged to be comparable to primary care populations. It will be used by the USPSTF to update its 2013 recommendation on screening for alcohol misuse in primary care. The current review uses the terminology of “unhealthy” use rather than “misuse” in accordance with the ASAM, which defined “unhealthy” use as any use that increases the risk or likelihood of health consequences (hazardous use), or that has already led to health consequences (harmful use), including a diagnosis of alcohol use disorder.

Key Questions and Analytic Framework

In consultation with members of the USPSTF, we developed key questions (KQs) and an analytic framework (Appendix A Figure 1) to guide our review.

1. a. Does primary care screening for unhealthy alcohol use in adolescents and adults, including pregnant women, reduce alcohol use or improve other risky behaviors?
   b. Does primary care screening for unhealthy alcohol use in adolescents and adults, including pregnant women, reduce morbidity or mortality or improve other health, social, or legal outcomes?
2. What is the accuracy of commonly used instruments to screen for unhealthy alcohol use?
3. What are the harms of screening for unhealthy alcohol use in adolescents and adults, including pregnant women?
4. a. Do counseling interventions to reduce unhealthy alcohol use, with or without referral, reduce alcohol use or improve other risky behaviors in screen-detected persons?
   b. Do counseling interventions to reduce unhealthy alcohol use, with or without referral, reduce morbidity or mortality or improve other health, social, or legal outcomes in screen-detected persons?
5. What are the harms of interventions to reduce unhealthy alcohol use in screen-detected persons?

Data Sources and Searches

We developed a search strategy designed to capture relevant literature published from 6 months prior to date of the search in the previous USPSTF review to identify newly published studies of screening and of counseling interventions (Appendix A). We then searched the following databases for relevant English-language literature published between January 1, 2011, and October 12, 2017: MEDLINE, PubMed (for publisher-supplied records only), PsycINFO, and the Cochrane Central Register of Controlled Trials. A research librarian developed and executed
the search, which was peer-reviewed by a second research librarian.

In addition, we evaluated all relevant studies included in the previous reviews for inclusion in the current review, as well as selected studies from the “excluded studies” appendix. We also examined the reference lists of other previously published reviews, meta-analyses, and primary studies to identify additional potential studies for inclusion. We supplemented our searches with suggestions from experts and articles identified through news and table-of-contents alerts. We also searched ClinicalTrials.gov (https://ClinicalTrials.gov/) for ongoing trials. We imported the literature from these sources directly into EndNote® X7 (Thomson Reuters, New York, NY).

**Study Selection**

We developed specific inclusion criteria to guide our study selection (Appendix A Table 2). For key questions addressing benefits and harms of screening (KQs 1 and 3) and treatment (KQs 4 and 5), we included randomized controlled trials (RCTs), including cluster randomized trials, and nonrandomized controlled trials that included a usual care, no intervention, minimal control, or attention control comparison group. For KQ2 we included studies of test accuracy reporting sensitivity and specificity compared with a structured or semistructured clinical interview. We excluded prospective and retrospective cohort studies, case control studies, time series studies, before-after studies with no comparison group, cross-sectional studies, case studies, case series, and editorials/commentaries.

We included studies conducted among adolescents or adults age 12 years or greater. For KQs 1-3, studies were required to be among participants who were not selected on the basis of alcohol use or a related behavior. For KQs 4 and 5, studies had to have at least half of their enrolled sample recruited via population-based screening, operationalized as individual outreach to members of a defined population (or a random or consecutive sample) who had been identified as potentially eligible to complete a standardized brief instrument. Additionally, studies of participants with alcohol dependence or severe AUD (or >50% of the enrolled sample having alcohol dependence/severe AUD) were excluded. Other population exclusions included studies limited to treatment-seeking individuals, those with concomitant psychotic disorders, those presenting in an emergency setting, and others not generalizable to primary care (e.g., inpatients, those court-mandated to treatment, those who are incarcerated).

We required that studies screen for alcohol use using a brief standardized instrument or set of questions. For KQ2 we limited the evidence to the most widely used screening instruments and those most feasible for application in primary care. This included those identified in the previous review as having the best evidence to support their use (AUDIT, AUDIT-C, SASQ) and those named in national-level recommendations related to screening for unhealthy alcohol use (AUDIT-C, SASQ). We also included variations of the AUDIT and AUDIT-C such as the USAUDIT/USAUDIT-C and those translated to other languages. Additionally, we selected instruments that target important subpopulations (adolescents [NIAAA 2-item screener, BSTAD], pregnant women [TWEAK, T-ACE], or older adults [CARET]), or that cover both drug and alcohol use (ASSIST). We did not, however, examine the CAGE questionnaire, despite its fairly widespread use in clinical trials of alcohol treatment, since it is not sensitive to lower-
level hazardous use and has not performed well with adolescents and young adults.77, 78 We did not limit evidence related to benefits or harms of unhealthy alcohol screening or treatment (KQ1, KQ3-5) on the basis of the screening instruments used in those studies; any screening instrument was accepted for these key questions.

To be included in this review, test performance (KQ2) studies were required to evaluate their screening tests against a reference standard, rather than another screening instrument. For reference standards we accepted structured or semi-structured interviews assessing alcohol use disorders and/or detailed quantity and frequency assessment, or computer-based versions of structured assessments of either alcohol use disorders or detailed alcohol quantity and frequency assessments. In addition, we excluded studies that assembled “clean” case and control groups, such as individuals being treated for alcohol use disorders (cases) and a community sample with no history of alcohol treatment (controls).

Intervention studies (KQs 1, 3, 4, 5) were required to report alcohol use as an outcome, such as frequency and/or quantity of use, abstinence, score on an instrument measuring severity of unhealthy use, or meeting criteria for alcohol use disorder. We required a minimum of six months of followup for all populations except pregnant women, who had no minimum followup requirement. We included interventions that were conducted in or recruited from primary care or a health care system or that we judged could feasibly be implemented in or referred from primary care. Eligible settings included primary care clinics; prenatal clinics; obstetrics/gynecology clinics; specialty medical treatment settings (e.g., diabetes management, dialysis clinics); and research clinics/offices, homes, or other community settings, including electronic or computer-based screening. For KQs 4 and 5, we required that screening to identify eligible participants must have taken place in settings comparable to primary care with a defined population (e.g., primary care clinic, Special Supplemental Nutrition Program for Women, Infants, and Children [WIC], college freshmen orientation). Screening that took place in behavioral/mental health clinics, substance abuse treatment centers, emergency department/trauma centers, worksites (including occupational screening), inpatient/residential facilities, or other institutions (e.g., correctional facility) were excluded. We focused on studies of counseling to reduce unhealthy alcohol use, with or without referral, and were open to a variety of approaches (e.g., brief advice, personalized normative feedback, motivational interviewing, cognitive behavioral therapy), strategies (e.g., action plans, diaries), delivery methods (e.g., face-to-face, electronic), length of contact (e.g., brief, extended), providers (e.g., medical, health educators, peers), and number of contacts (e.g., single, multiple). Interventions to prevent initiation of use among nonusers were not included. Since pharmacotherapy is primarily relevant to patients with severe alcohol-use disorder, studies of pharmacotherapy treatment were excluded.

Two reviewers independently reviewed titles and abstracts for potential inclusion, then two reviewers reviewed the full-text articles. Discrepancies were resolved via discussion and third-party consultation as needed. Title, abstract, and full-text review were conducted in DistillerSR (Evidence Partners, Ottawa, Canada).
Quality Assessment and Data Abstraction

Two reviewers applied USPSTF design-specific criteria (Appendix A Table 3) and supplemented it with criteria from the Quality Assessment of Diagnostic Accuracy Studies to assess the methodological quality of all eligible studies. We assigned each study a quality rating of “good,” “fair,” or “poor.” Discordant quality ratings were reviewed and discussed; a third reviewer adjudicated as needed. Studies rated as “poor” quality were excluded from the review.

For intervention trials, good-quality studies were those that met all or nearly all of the specified quality criteria (e.g., comparable groups were assembled initially and maintained throughout the study, and followup was 90% or higher), whereas fair-quality studies did not meet all of these criteria but did not have serious threats to their internal validity related to the design, execution, or reporting of the study. Intervention studies rated as poor quality generally had several important limitations, including at least one of the following risks of bias: very high attrition (generally >40%), differential attrition between intervention arms (generally >20%); lack of baseline comparability between groups without adjustment; or issues in trial conduct, analysis, or reporting of results that put the validity of the findings in doubt (e.g., possible selective reporting, inappropriate exclusion of participants from analyses, and questionable validity of randomization and allocation concealment procedures). For studies of test performance, good-quality studies recruited patients consecutively or randomly; administered the index test blinded to, or at least prior to, the reference standard; used a reference standard that could accurately classify the target condition; interpreted the reference standard independently from the screening test; and administered the screening test and reference standard on the same day to all participants.

For all of the included studies, one reviewer extracted key elements into standardized abstraction forms in DistillerSR (Evidence Partners, Ottawa, Canada). A second reviewer checked the data for accuracy. For each study, we abstracted general characteristics of the study (e.g., author, year, study design), clinical and demographic characteristics of the sample and setting (e.g., age, race/ethnicity, baseline clinical characteristics, setting, country), analytic methods, and results.

For test performance studies (KQ2), we abstracted details of the reference standards and screening instruments. We abstracted the optimal cutoff for each screening test, either as defined by the author or selected by the reviewer as the best balance of sensitivity and specificity reported. We also abstracted the cutoff of ≥8 for AUDIT, ≥3, 4, and 5 for AUDIT in United States primary care studies, ≥3 for AUDIT-C in women, and ≥4 for AUDIT-C in men. The outcomes of interest were sensitivity and specificity, which we calculated based on provided 2x2 tables if they were not directly reported.

For intervention characteristics of KQ 4 and 5 trials, we abstracted detailed information about specific components: setting, mode of delivery (i.e., in-person, telephone, electronic, or print); therapeutic or intervention approach (e.g., cognitive behavioral therapy, motivational interviewing), duration, number, and length of sessions; providers and provider training; and adherence. We determined the intensity of the intervention based on the number and length of contacts and assigned one of the following designations: very brief (single contact ≤5 minutes), brief (single contact, up to 15 minutes), extended (single contact, greater than 15 minutes), brief
multicontact (multiple contacts, up to 15 minutes each), or extended multicontact (multiple contacts, one or more of them greater than 15 minutes).

**Data Synthesis and Analysis**

We created summary tables for all KQs showing study, population, and intervention characteristics (if applicable) and outcomes for qualitative evidence synthesis. Studies were grouped according to population: adolescents (ages ~12 to 18), young adults (~18 to 25), general adult populations (18 or older), older adults (~65 or older), and pregnant and postpartum women. We used these tables along with forest plots of results to examine data for consistency, precision, and, for intervention trials, the relationship of effect size with key potential modifiers such as population, treatment contact time, control group alcohol use at baseline, and publication date. If available, we abstracted and examined results reported in the following subgroups: sex, age, race/ethnicity, socioeconomic status (SES) group, pregnant women, and those with specific concurrent substance use, specific severity of disorder, mental health condition, or at a particular level of readiness to change.

For studies on the accuracy of screening instruments (KQ 2), we calculated confidence intervals (CIs)\(^{81, 82}\) in Stata version 13.1 (Stata Corp LP, College Station, TX), using data from contingency tables that included true positives, false positives, false negatives, and true negatives. If these data were not reported directly, we created contingency tables based on the total sample size, number of persons with the diagnosis according to the reference standard, sensitivity, and specificity. No pooled analyses were performed due to the small number of studies that were available for each combination of study populations, screening tests, reported screening test cutoffs, and target conditions. We report a range of sensitivity and specificity across eligible studies to provide an overall description of findings. While many conditions were reported in our included studies, we focused our analysis on (a) the full spectrum of unhealthy use (including use in pregnant women) and (b) use disorder (DSM-IV abuse and dependence, or DSM-5 use disorder). Our primary analyses focused on the full spectrum of unhealthy use (exceeding limits, abuse, and dependence), although we also report data on exceeding limits alone in the detailed results. Data for other conditions, including dependence only (DSM-IV dependence or DSM-5 moderate/severe dependence), are in Appendix G and Appendix I.

For KQ4, we selected drinks per week as our primary outcome since it was by far the most commonly reported outcome. We converted all related outcomes to drinks per week, such as when provided with other time frames (e.g., drinks/month) or with grams or ethanol rather than drinks. We used the conversion factor of 14 grams of ethanol for one standard drink, since this is the definition of a standard drink in the United States.

We had sufficient data with acceptable comparability between studies to conduct meta-analysis with 40 trials altogether, across the four main alcohol-use outcomes of drinks per week, exceeding recommended limits, heavy use episodes, and abstinence (for pregnant women). Few health outcomes were reported in enough trials to consider pooling; however, we were able to conduct a meta-analysis of mortality and alcohol problems or consequences.
We ran random-effects models using the DerSimonian and Laird pooled estimate, which we felt was acceptable because most analyses either included more than 10 trials or had low statistical heterogeneity. For analyses that showed statistically significant pooled effects but had fewer than 10 trials and I² larger than 50 percent, we also ran a sensitivity analysis, using a more conservative profile likelihood model to see if statistical significance was sustained. If the profile likelihood model did not converge, we ran a restricted maximum likelihood (REML) analysis with the Knapp-Hartung correction for small samples. When trials only reported results separately for subgroups (e.g., males and females), we included entries for both subgroups in the meta-analysis. For outcomes with 10 or more trials in the meta-analysis (drinks per week, exceeding recommended limits, and heavy use episodes), we generated funnel plots and ran Egger’s test to examine funnel plot asymmetry to explore small study effects, which can be an artifact of publication bias. Additionally, for drinks per week, which included 31 trials (and 36 separate entries) and had considerable statistical heterogeneity (I²=64%), we conducted meta-regression and sensitivity analyses to explore factors that were associated with effect size. We used Stata version 13.1 (StataCorp LP, College Station, TX) for all analyses.

Grading the Strength of the Body of Evidence

We graded the strength of the overall body of evidence for each key question. We adapted the Evidence-based Practice Center approach, which is based on a system developed by the Grading of Recommendations Assessment, Development and Evaluation (GRADE) Working Group. Our method explicitly addresses four of the five Evidence-based Practice Center-required domains: consistency (similarity of effect direction and size), precision (degree of certainty around an estimate), reporting bias (potential for bias related to publication, selective outcome reporting, or selective analysis reporting), and study quality (i.e., study limitations). We did not address the fifth required domain—directness—as it is implied in the structure of the key questions (i.e., pertains to whether the evidence links the interventions directly to a health outcome).

Consistency was rated as reasonably consistent, inconsistent, or not applicable (e.g., single study). Precision was rated as reasonably precise, imprecise, or not applicable (e.g., no evidence). Reporting bias was rated as suspected, undetected, or not applicable (e.g., when there was insufficient evidence for a particular outcome). Study quality reflects the quality ratings of the individual trials and indicates the degree to which the included studies for a given outcome have a high likelihood of adequate protection against bias. The body of evidence limitations field highlights important restrictions in answering the overall key question (e.g., lack of replication of interventions, nonreporting of outcomes important to patients).

We graded the overall strength of evidence as high, moderate, or low. “High” indicates high confidence that the evidence reflects the true effect and that further research is very unlikely to change our confidence in the estimate of effects. “Moderate” indicates moderate confidence that the evidence reflects the true effect and that further research may change our confidence in the estimate of effect and may change the estimate. “Low” indicates low confidence that the evidence reflects the true effect and that further research is likely to change our confidence in the estimate of effect and is likely to change the estimate. A grade of “insufficient” indicates that
evidence is either unavailable or does not permit estimate of an effect. Two independent reviewers rated each key question according to consistency, precision, reporting bias, and overall strength of evidence grade. We resolved discrepancies through consensus discussion involving more reviewers.

**Expert Review and Public Comment**

The draft Research Plan was posted for public comment on the USPSTF Web site from August 25, 2016, to September 21, 2016. In response to public comments, the USPSTF narrowed the scope of the review to target nondependent, unhealthy alcohol use. Based on this change, the USPSTF also modified the inclusion criteria to exclude test performance studies of the CAGE questionnaire (since it is not used for identifying the full spectrum of at-risk alcohol use) and pharmacotherapy intervention studies (since these are typically reserved for persons with alcohol dependence). In addition, the USPSTF revised the inclusion criteria to include studies limited to persons with concomitant, nonpsychotic mental health disorders such as depression and anxiety disorders. The USPSTF made other minor modifications and clarifications as appropriate, such as expanding some outcomes (“school/educational outcomes” rather than “school performance”), including the ICD code system as a way to identify persons with the condition, and noting that interventions to prevent initiation of alcohol use in adolescents are excluded. A final research plan was posted on the USPSTF’s Web site on October 20, 2016. This full draft report was shared with invited expert reviewers and federal partners. We compiled the comments received from these invited experts and addressed them in the report when appropriate.

**USPSTF Involvement**

We worked with six USPSTF members at key points throughout this review, particularly when determining the scope and methods for this review and developing the Analytic Framework and KQs. After revisions reflecting the public comment period, the USPSTF members approved the final analytic framework, KQs, and inclusion and exclusion criteria. AHRQ funded this review under a contract to support the work of the USPSTF. An AHRQ Medical Officer provided project oversight, reviewed the draft report, and assisted in the external review of the report.
Chapter 3. Results

Literature Search

We reviewed 17,149 abstracts and 570 full-text articles for all KQs (Appendix A Figure 2), and included 114 studies, reported in 160 publications. The list of included studies and excluded studies (with reasons for exclusion) are available in Appendix E and Appendix F, respectively.

Key Question 1a. Does Primary Care Screening for Unhealthy Alcohol Use in Adolescents and Adults, Including Pregnant Women, Reduce Alcohol Use or Improve Other Risky Behaviors?

Key Question 1b. Does Primary Care Screening for Unhealthy Alcohol Use in Adolescents and Adults, Including Pregnant Women, Reduce Morbidity or Mortality or Improve Other Health, Social, or Legal Outcomes?

We found no trials that examined the direct effect of screening for unhealthy alcohol use on alcohol use or on health, social, or legal outcomes.

Key Question 2. What Is the Accuracy of Commonly Used Instruments to Screen for Unhealthy Alcohol Use?

Included Studies

We identified 45 studies78, 87-130 (reported in 56 publications78, 87-141) (Table 4) that addressed the accuracy of screening instruments (KQ2): 10 in adolescents,95, 96, 99, 108, 110, 112, 113, 117, 124, 125 5 in young adults,78, 89, 103, 114, 121 27 in general adult populations,87, 90-93, 97, 98, 100-102, 104-107, 109, 111, 115, 116, 118-120, 122, 123, 126-128, 130 one in older adults,88 and two in pregnant94 or postpartum women.129

One study in a general adult population provided subgroup analyses of pregnant women and older adults100, 133 and one study of participants ages 12 to 20 years provided subgroup analyses of young adults (ages 18 to 20).96 The majority of studies were conducted in the United States (28/45 [62%]) and recruited patients from primary care (23/45 [51%]) (Table 5). The number of screened participants ranged from 95 to 166,165. A variety of one- or two-item screening tests was used in the included studies, as well as the AUDIT, AUDIT-C, and ASSIST. The one- or two-item screening tools addressed a variety of specific targets, such as typical or maximum drinks per drinking day (quantity), number of unhealthy drinking days over a specified time period (frequency), or typical total number of drinks over a specific time period (quantity x frequency). Response categories and cutoffs also varied. Studies sometimes assigned a certain
number of drinks to be the cutoff (e.g., more than four drinks on one occasion at any time during the time window). Others used questions with Likert-type response categories, such as Item 3 from the AUDIT-C (often referred to as the AUDIT-3), which asks, “How often do you have six or more drinks on one occasion?” and has response categories 0 (never), 1 (less than monthly), 2 (monthly), 3 (weekly), and 4 (daily or almost daily); for a given study, a positive screening value may be 1, 2, or 3.

Reference standards used in the included studies were most commonly structured diagnostic interviews (e.g., Composite International Diagnostic Interview [CIDI], Alcohol Use Disorder and Associated Disabilities Interview Schedule [AUDADIS], Mini International Neuropsychiatric Interview Plus [MINI-Plus]), and sometimes the interview was used in combination with other instruments (e.g., with the ASSIST to identify the full spectrum of unhealthy use) or with the Timeline Followback (TLFB). The majority of the studies were fair quality (28/45 [62%]). Among the studies that were rated as fair quality, the most common reasons for increased risk of bias included: not reporting enough information regarding the order and timing of the reference standard and screening test; not clearly reporting on whether the researchers had knowledge of the index test results during the administration and interpretation of the reference standard; not presenting a range of cutoff values or an a priori threshold; and/or not reporting whether participant recruitment was random or consecutive.

Summary of Results

Table 6 summarizes the test accuracy of the most commonly used screening instruments (one- or two-item questions, AUDIT-C, and AUDIT) for detecting full spectrum of unhealthy alcohol use (including exceeding daily or weekly limits, exceeding heavy use episode limits, and meeting criteria for AUD) and AUD (any level of severity, including both abuse and dependence). Forest plots show study-level results for detecting unhealthy use (Figures 1-7) and AUD (Figures 8-13). In addition, detailed information on the use of these instruments to detect alcohol dependence or severe AUD is available in Appendix G.

For adolescents, just one study (n=225) in a German high school reported on the test accuracy for detecting the full spectrum of unhealthy alcohol use (Figure 4), finding a sensitivity of 0.73 (95% CI, 0.60 to 0.83) and specificity of 0.81 (95% CI, 0.74 to 0.86) for the optimal cutoff of 5 or higher on the AUDIT-C (males and females combined). Multiple studies demonstrated good test accuracy of one- or two-item questions and the AUDIT for detecting AUD. For example, the NIAAA-recommended single question (In the past year, on how many days have you had more than a few sips of beer, wine, or any drink containing alcohol?) had sensitivity ranging from 0.87 to 1.00 (95% CI range, 0.76 to 1.0) and specificity 0.84 to 0.94 (95% CI range, 0.82 to 0.97, k=3, n=2,486, Figure 8), and other one- or two-item screeners showed similar results. All five studies addressing one- or two-item screeners were conducted in primary care settings in the United States, and in several studies the samples were comprised primarily of black and Hispanic youth.

For adults, studies of the NIAAA-recommended single-item question (How many times in the past year have you had 5/4 [males/females] or more drinks in a day?) reported sensitivity of
0.73 to 0.88 (95% CI range, 0.65 to 0.89) and specificity of 0.74 to 1.0 (95% CI range, 0.69 to 1.0) for detecting unhealthy alcohol use (k=4, n=44,461, Figure 1, labeled “5/4+ drinks”). All of these studies were conducted in the United States, primarily in primary care settings. Other one- or two-item screeners generally showed sensitivities of 0.70 or higher, although the standard of ≥6 drinks per occasion tended to have lower sensitivity than the ≥5/4 drinks standard, often with nonoverlapping confidence intervals. Other adult populations (young adults, older adults, pregnant women) had results in similar ranges. When used for detecting AUD instead of the full spectrum of unhealthy use, the ranges were largely overlapping but shifted slightly higher for sensitivity and lower for specificity.

For the AUDIT-C, sensitivity for detecting unhealthy alcohol use in adults was similar to the one- or two-item screeners, excluding one VA-based study in human immunodeficiency virus (HIV) positive patients and matched controls\textsuperscript{119} that had substantially lower sensitivity. In most studies, the range of sensitivities was 0.73 to 0.97 for females (95% CI range, 0.62 to 0.99, k=5, n=2,714, Figure 2) and 0.82 to 1.0 for males (95% CI range, 0.75 to 1.0, k=4, n=1,038, Figure 3) at the standard cutoffs of ≥3 for females and ≥4 for males, but the range of reported specificity was much wider (0.28 to 0.91 [95% CI range, 0.21 to 0.93] and 0.34 to 0.89 [95% CI range, 0.25 to 0.92], for females and males, respectively). A number of studies reported sensitivities of 0.80 or high at optimal cutoffs on the AUDIT-C, with associated specificities generally in range of mid-0.70s to mid-0.80s (Figure 4). Results generally showed similar ranges when detecting AUD rather than the full spectrum of unhealthy alcohol use, except with some higher specificity values at the standard cutoffs. Evidence on the use of the AUDIT-C was very sparse in the adult subpopulations of younger adults, older adults, and pregnant women.

For the AUDIT, when using the recommended cutoff of ≥8, studies reported a wide range of sensitivity for detecting unhealthy alcohol use in general adult populations (0.38 to 0.73, 95% CI range, 0.33 to 0.84) but high specificity (0.89 to 0.97, 95% CI range, 0.84 to 0.98, k=7, n=8,852, Figure 5). Sensitivity was relatively high (0.82) in young adults at the standard cutoff of ≥8, but data were sparse in this population (k=2, n=660). In many studies, sensitivity improved at lower cutoffs. Studies conducted in U.S.-based primary care settings showed a more optimal balance of sensitivity and specificity at cutoffs of 3, 4, or 5 (sensitivity: 0.64 to 0.86 [95% CI range, 0.57 to 0.91], specificity: 0.74 to 0.94 [95% CI range, 0.68 to 0.95], k=3, n=2782, Figure 7). Both sensitivity and specificity values tended to be wider ranging across studies for detecting AUD than for detecting unhealthy use when using the AUDIT.

For all studies, subgroup analyses commonly identified different optimal cutoffs for different subgroups. In several instances, optimal cut-points were lower for females than for males, for blacks than for whites, and for the very young and older ages versus general adults. However, with little replication and sometimes conflicting results, evidence does not clearly support any specific alternate cut-points for the subgroups and instruments explored. One study\textsuperscript{103} among young adults reported test accuracy for male and female subgroups to detect unhealthy alcohol use employing the AUDIT and AUDIT-C. The optimal cutoff for the AUDIT was ≥8 for both sexes; for the AUDIT-C, females had a lower cutoff than males (≥5 vs. ≥7). Another study among young adults found lower optimal cutoffs for the AUDIT and AUDIT-C for females versus males.\textsuperscript{121} For adults, four studies found lower optimal cut-points for females than males on both the AUDIT and the AUDIT-C,\textsuperscript{87, 109, 116, 128} however, one of these\textsuperscript{128, 134} reported no
difference in performance characteristics by sex at the standard cutoffs for the AUDIT. Three studies examining single-item screeners found no difference in test accuracy between males and females but one study found lower optimal cutoffs for females.

Race/ethnicity differences were suggested in some, but not all, studies. One study among young adults reported the same cutoffs for the AUDIT for white and black males, but lower for black females versus white females. The same study reported lower cutoffs for the AUDIT-C for black versus white participants. For general adults, race/ethnicity differences in the optimal cutoffs were reported for single-item screeners in one study with higher optimal cutoffs for American Indian, white, and Hispanic participants versus Asian and black participants but no statistically significant difference was found for race/ethnicity in two other studies. Volk and colleagues reported no difference by race/ethnicity for the AUDIT, and while the test accuracy in the same group of participants varied by race/ethnicity for the AUDIT-C, the authors did not recommend using different cutoffs for race/ethnicity in practice.

Socioeconomic status was examined in two studies of single-item screening tests, with no difference reported.

In general, older adults tended to have lower optimal cutoffs than the general adult population. Among adolescents, one study suggested lower cutoffs to detect alcohol dependence for single-item screeners, but in another study, the optimal cutoffs remained the same for younger (12 to 14 years) and older (15 to 17 years) adolescents to detect AUD. When comparing adolescents (12 to 17 years) to young adults (18 to 20 years) within the same study, the optimal cutoffs to detect AUD were higher for young adults.

**Detailed Results**

**Adolescents**

**Study and Population Characteristics**

Five good-quality and five fair-quality studies recruited adolescent participants, usually 12 to 17 years of age. Seven studies were conducted with United States primary care patients; one recruited a community-based sample in the United States, and the two studies conducted outside the United States (Germany, Chile) recruited participants from schools. Studies ranged in size from 95 to 166 participants; all but one of the studies had less than 1,600 participants. The mean age was 15 or 16 years in six studies; four studies did not report mean age. The number of females ranged from 44 to 68 percent. Race/ethnicity was reported in the eight U.S.-based studies. Three studies had a majority of white participants (62% to 93%), three studies had a majority of black participants (51% to 93%), and two others had a majority of nonwhite participants (82% to 85%). One study restricted eligibility to adolescents who had been diagnosed for a year or longer with type 1 diabetes, asthma, cystic fibrosis, inflammatory bowel disease, or juvenile idiopathic arthritis.
Only one study reported the prevalence of unhealthy alcohol use: 24.9 percent. In seven studies, the prevalence of AUD ranged from 2.9 to 7.6 percent (dependence ranged from 2.2% to 2.5% in two studies). One study recruiting students from a comprehensive school in Germany, had a much higher prevalence of AUD at 20.0 percent (dependence 3.1%).

One study evaluated the test accuracy for identifying unhealthy use, eight studies for AUD, and four studies for dependence. Four studies assessed the test accuracy of the AUDIT, one studied the AUDIT-C, one studied the ASSIST, and six studies examined various one- or two-item screeners. For all conditions, all studies used a structured clinical interview (e.g., CIDI, Adolescent Drinking Index [ADI], Diagnostic Interview Schedule for Children, Version Four [DISC-IV]) as the reference standard.

Full Spectrum of Unhealthy Alcohol Use

One- or two-item. No studies among adolescents reported on test accuracy for using a one- or two-item test to screen for the full spectrum of unhealthy alcohol use. One study using a one- or two-item test to screen for those exceeding limits reported a sensitivity of 0.56 (95% CI, 0.51 to 0.61) and specificity of 0.92 (95% CI, 0.90 to 0.93) (Appendix H Figure 5, Appendix I Table 4).

AUDIT-C. One study reported a sensitivity of 0.73 (95% CI, 0.60 to 0.83) and specificity of 0.81 (95% CI, 0.74 to 0.86) for the optimal cutoff of 5 or higher for males and females combined (Figure 4, Appendix I Table 1) in a sample with high levels of AUD. One study reported sensitivity of 0.85 (95% CI, 0.69 to 0.93) and specificity of 0.77 (95% CI, 0.71, 0.82) at the optimal cutoff of ≥5 to detect those exceeding limits (Appendix H Figure 6, Appendix I Table 4).

AUDIT. The same study (n=225) reported a sensitivity of 0.66 (95% CI, 0.53 to 0.77) and specificity of 0.86 (95% CI, 0.80 to 0.90) when using the standard cutoff of 8 or higher (Figure 5, Appendix I Table 1). The optimal cutoff reported in this study was 6 or higher, with a sensitivity of 0.79 (95% CI, 0.66 to 0.87) and specificity of 0.79 (95% CI, 0.73 to 0.85) (Figure 6, Appendix I Table 1). Two studies reported sensitivity ranging from 0.85 to 0.96 (95% CI range, 0.69 to 1.0) and specificity ranging from 0.63 to 0.73 (95% CI range, 0.48 to 0.79) to detect those exceeding limits using the AUDIT at the optimal cutoffs of 3 and 6 (Appendix H Figure 7, Appendix I Table 4).

ASSIST. No studies among adolescents on test accuracy for using the ASSIST to screen for the full spectrum of unhealthy alcohol use.

Alcohol Use Disorder

One- or two-item. Five studies (n=3,564) reported test accuracy for four variations of a one- or two-item screening test (Figure 8, Appendix I Table 2), with sensitivity ranging from 0.87 to 1.0 (95% CI range, 0.68 to 1.00) and specificity ranging from 0.84 to 0.95 (95% CI range, 0.82 to 0.97). Three studies (n=2,486) followed a screening
approach recommended by the NIAAA that asks about friends’ and personal use of alcohol; the sensitivity ranged from 0.87 to 1.00 (95% CI range, 0.76 to 1.0) and specificity ranged from 0.84 to 0.94 (95% CI range, 0.82 to 0.97).

AUDIT-C. One study\textsuperscript{124} (n=225) reported a sensitivity of 0.76 (95% CI, 0.61 to 0.86) with a corresponding specificity of 0.78 (95% CI, 0.71 to 0.83) at the optimal cutoff of ≥5 for males and females combined (Figure 11, Appendix I Table 2).

AUDIT. Three studies examined the test accuracy of the AUDIT at a cutoff of ≥8 (Figure 12, Appendix I Table 2).\textsuperscript{99, 113, 124} Sensitivity was similar for two studies at 0.70 (95% CI, 0.57 to 0.81)\textsuperscript{99} and 0.71 (95% CI, 0.57 to 0.82),\textsuperscript{124} with widely ranging proportion with AUD (3.9% and 20%); the third study reported a sensitivity of 0.54 (95% CI, 0.38 to 0.69).\textsuperscript{113} Specificity ranged from 0.84 to 0.97 (95% CI range, 0.78 to 0.98). A lower optimal cutoff was reported for two studies, at ≥3\textsuperscript{113} and ≥6.\textsuperscript{124} Sensitivity was higher (0.84 and 0.88; 95% CI range, 0.71 to 0.97), but specificity decreased (0.77; 95% CI range, 0.71 to 0.83) for these lower cutoffs (Figure 13). One study\textsuperscript{113} conducted with a United States primary care sample also reported the test accuracy of the AUDIT at a cutoff of ≥5 with sensitivity of 0.73 (95% CI, 0.58 to 0.87) and specificity of 0.88 (95% CI, 0.85 to 0.91) (Figure 7, Appendix I Table 2).

ASSIST. One study\textsuperscript{108} used the ASSIST with a cutoff of ≥2 to screen for DSM-5 AUD; sensitivity was 1.00 (95% CI, 0.86 to 1.00) and specificity was 0.79 (95% CI, 0.75 to 0.82) (Appendix I Table 2).

Young Adults

Study and Population Characteristics

Four good-quality studies\textsuperscript{78, 96, 103, 114} and two fair-quality studies\textsuperscript{89, 121} recruited young adults. One of the good-quality studies included adolescents ages 12 to 20 and reported results for a young adult subgroup (ages 18 to 20 years).\textsuperscript{96} Five studies were conducted in the United States, three from college/university settings,\textsuperscript{103, 114, 121} one from primary care,\textsuperscript{96} and one from an sexually transmitted infection (STI) clinic.\textsuperscript{78} The sixth study was conducted at a university in Belgium.\textsuperscript{89} Mean age ranged from 18 to 21 years, and the proportion of female participants ranged from 45 to 68 percent. Three studies\textsuperscript{103, 114, 121} had a majority of white participants (64% to 90%) and one study\textsuperscript{78} had 46 percent white and 49 percent black participants. Race/ethnicity was not reported in the Belgian study or for the subgroup of young adults. Sample size ranged from 251 to 3,564 participants. SES was not reported in any of the six included studies.

Two studies evaluated the test accuracy for identifying unhealthy use (prevalence ranged from 28.1% to 52%),\textsuperscript{103, 114} four studies for AUD (prevalence ranged from 10.0% to 43.4%),\textsuperscript{78, 89, 96, 114} and two for dependence (Appendix G).\textsuperscript{89, 121} Five studies assessed test accuracy of the AUDIT, two evaluated the AUDIT-C,\textsuperscript{103, 121} and one examined a variety of one- or two-item screening questions.\textsuperscript{96} For unhealthy use, one study used a structured clinical interview and one used the TLFB as reference standards. For use disorder and dependence, all studies used a structured clinical interview for the reference standard.
Full Spectrum of Unhealthy Alcohol Use

One- or two-item. No included studies focused on young adults reported on test accuracy for using one- or two-item test to screen for the full spectrum of unhealthy alcohol use.

**AUDIT-C.** One study reported sensitivity of 0.98 (95% CI, 0.93 to 0.99) and specificity of 0.47 (95% CI, 0.38 to 0.56) for females at a cutoff of ≥3 (Figure 2, Appendix I Table 6). The optimal cutoff in this study was ≥5 for females (sensitivity 0.82 [95% CI, 0.73, 0.88]; specificity 0.82 [95% CI, 0.74 to 0.88]) (Figure 4). For males and a cutoff of ≥4, sensitivity was 0.97 (95% CI, 0.92 to 0.99) and specificity was 0.40 (95% CI, 0.30 to 0.50) (Figure 3). The optimal cutoff was ≥7 for males (sensitivity 0.80 [95% CI, 0.71 to 0.86]; specificity 0.88 [95% CI, 0.79 to 0.93]) (Figure 4).

**AUDIT.** Two studies assessed the test accuracy of the AUDIT to screen for unhealthy alcohol use (Appendix I Table 6). At a cutoff of ≥8, also the optimal cutoff for one study, sensitivity was 0.82 in both studies (95% CI range, 0.72 to 0.88) and specificity was 0.79 and 0.78 (95% CI range, 0.72 to 0.84) (Figure 5). The optimal cutoff was ≥7 for one study (sensitivity 0.88 [95% CI, 0.79 to 0.93]; specificity 0.70 [95% CI, 0.64 to 0.76]) (Figure 6).

**ASSIST.** No studies among young adults reported on test accuracy for using the ASSIST to screen for the full spectrum of unhealthy alcohol use.

Alcohol Use Disorder

One- or two-item. One study (n=251) assessed the test accuracy of three variations of a one- or two-item screening question to screen for AUD, assessing frequency (drinking days in the previous year), quantity (drinks per drinking day), and the combination (total drinks consumed in the previous year) (Figure 8, Appendix I Table 7). Sensitivity ranged from 0.81 to 0.92 (95% CI range, 0.61 to 0.98) and specificity ranged from 0.75 to 0.80 (95% CI range, 0.69 to 0.85). Total drinks in the previous year had the highest sensitivity but lowest specificity.

**AUDIT-C.** No included studies that focused on young adults reported on test accuracy for using the AUDIT-C to screen for AUD.

**AUDIT.** Two studies reported a cutoff of ≥8, with sensitivities of 0.68 (95% CI, 0.60 to 0.75) and 0.82 (95% CI, 0.74 to 0.89) and specificities of 0.75 (95% CI, 0.68 to 0.81) and 0.72 (95% CI, 0.65 to 0.77), respectively (Figure 12, Appendix I Table 7). The optimal cutoff ranged from ≥6 to ≥8 in three studies reporting test accuracy for any cutoffs (sensitivity 0.73 to 0.82 [95% CI range, 0.65 to 0.89]; specificity 0.67 to 0.78 [95% CI range, 0.60 to 0.79]) (Figure 13).

**ASSIST.** No studies of young adults reported on test accuracy for using the ASSIST to screen for AUD.
General Adults

Study and Population Characteristics

Eight good-quality $^{90, 92, 100, 104, 105, 115, 120, 127}$ and 19 fair-quality studies $^{87, 91, 93, 97, 98, 101, 102, 106, 107, 109, 111, 116, 118, 122, 123, 126, 128, 130}$ recruiting adults were included. Fifteen studies were conducted in the United States; the other 12 were conducted in Europe (1 each in Switzerland/France, Netherlands, United Kingdom, and Germany; 2 each in Finland and Italy; 3 in Spain) or Australia (k=1). Nine studies recruited from United States primary care. Mean age ranged from 26 to 52 years. One study recruited exclusively females $^{92}$ and one study recruited exclusively males $^{119}$; otherwise, the proportion of female participants ranged from 20.3 to 74.8 percent. Three studies recruited participants from the VA $^{92, 98, 119}$ Six studies limited their recruitment or analysis to participants who the study categorized as current drinkers $^{90, 93, 105, 119, 123, 126}$ Three studies recruited participants with diagnoses or symptoms of anxiety or depression $^{90, 91, 116}$; one recruited HIV positive participants $^{119}$; two of these studies also recruited controls that did not have the disease $^{91, 119}$ Sample size ranged from 124 to 43,093 participants. Race/ethnicity was reported in 12 studies, 11 of the 12 studies were based in the United States. Six studies had a majority of white participants $^{92, 97, 98, 104, 118, 126}$; six studies had higher proportions of other race/ethnic groups than whites, primarily black and Hispanic $^{115, 119, 120, 127, 128, 130}$ While socioeconomic status was not widely reported, six U.S.-based studies recruited participants of lower socioeconomic status, as indicated by recruitment setting, income, employment, and/or education $^{93, 111, 115, 120, 128, 130}$

Eleven studies $^{87, 102, 109, 116, 119, 120, 122, 123, 126-128}$ reported prevalence of unhealthy alcohol use, ranging from 7.9 to 53.2 percent; all but three of the 11 studies reported a prevalence of less than 33 percent $^{102, 116, 126}$ Across 16 studies $^{90, 93, 98, 100-102, 104, 105, 111, 115, 118, 120, 126-128, 130}$ prevalence of AUD ranged from 7.7 to 43.8 percent; 5 of the 16 studies reported AUD prevalence greater than 20 percent $^{93, 102, 104, 111, 126}$ Twelve studies evaluated the test accuracy for identifying unhealthy alcohol use, 16 studies for AUD, and 10 for alcohol dependence. Nineteen studies assessed test accuracy of the AUDIT, 15 evaluated the AUDIT-C, 12 evaluated one- or two-item screeners, and one evaluated the ASSIST $^{115}$

The reference standard varied depending on the condition, but nearly all studies used a structured diagnostic interview, at times with TLFB, Short Inventory of Problems (SIP) for alcohol, or the ASSIST. For AUD and alcohol dependence, all studies used a structured diagnostic interview, most frequently based on DSM-IV criteria. For unhealthy alcohol use, structured interview was often used in combination with the TLFB. In two studies $^{87, 116}$ the target condition was exceeding recommended limits (ignoring alcohol use disorder), and the reference standard was based on the TLFB only.

Full Spectrum of Unhealthy Alcohol Use

One- or two-item. Seven studies that recruited adults assessed the test accuracy of various one- or two-item screeners to screen for unhealthy alcohol use (Figure 1, Appendix I Table 10) $^{87, 100, 116, 119, 120, 126, 127}$ Across these studies, sensitivity ranged from 0.65 to 0.90 (95% CI range, 0.58 to
0.91) and specificity ranged from 0.68 to 1.0 (95% CI range, 0.64 to 1.0) (n=48,211). Four studies with a total of 44,461 participants assessed the test accuracy of a question on heavy episodic drinking recommended by the NIAAA (5/4+ drinks) and reported sensitivity ranging from 0.73 to 0.88 (95% CI range, 0.65 to 0.90) and specificity ranging from 0.74 to 1.0 (95% CI range, 0.69 to 1.0) at the optimal cutoff. In general, the instruments defining a positive screen as drinking six or more drinks on one occasion had lower sensitivity and higher specificity than those using the standard of 5/4 or more drinks (for males/females). Five studies used a one- or two-item test to screen for those exceeding limits and reported sensitivity ranging from 0.75 to 0.93 (95% CI range, 0.61 to 0.96) and specificity ranging from 0.72 to 0.91 (95% CI range, 0.68 to 0.93) at the optimal cutoff. An additional study recruiting male HIV patients and matched controls from the VA reported a sensitivity of 0.48 (95% CI, 0.39 to 0.57) and specificity of 0.94 (95% CI, 0.92 to 0.95) (Appendix H Figure 5, Appendix I Table 13).

**AUDIT-C.** Eight studies assessed the test accuracy of the AUDIT-C to screen for unhealthy alcohol use (Appendix I Table 10). In five studies reporting a cutoff of ≥3 for females, sensitivity ranged from 0.73 to 0.97 (95% CI range, 0.62 to 0.99) and specificity ranged from 0.28 to 0.91 (95% CI range, 0.21 to 0.93) (Figure 2). In four of the five studies reporting a cutoff of ≥4 for males, sensitivity ranged from 0.82 to 1.0 (95% CI range, 0.75 to 1.0) and specificity ranged from 0.34 to 0.89 (95% CI range, 0.25 to 0.92) (Figure 3). The remaining study recruited male patients from the VA and had much lower sensitivity at a cutoff of ≥4: 0.63 (95% CI, 0.55 to 0.69), with corresponding specificity of 0.90 (95% CI, 0.87 to 0.92). Optimal cutoffs ranged from ≥2 to ≥6 across eight studies; at times the optimal cutoffs differed by subgroup with the optimal cutoff for females lower than the optimal cutoff for males (Appendix I Table 10). The most frequently reported optimal cutoffs were ≥4 and ≥5. Across eight studies, sensitivity at the optimal cutoffs ranged from 0.74 to 0.92 (95% CI range, 0.62 to 0.98) and specificity ranged from 0.66 to 0.89 (95% CI range, 0.59 to 0.92) (Figure 4). One study that recruited male HIV positive patients and matched controls from the VA reported a lower sensitivity for the optimal cutoff, at 0.63 (95% CI, 0.55 to 0.69) with corresponding specificity of 0.90 (95% CI, 0.87 to 0.92). Seven studies used the AUDIT-C to screen for those exceeding limits, with sensitivity ranging from 0.74 to 1.0 (95% CI range, 0.64 to 1.0) and specificity ranging from 0.77 to 0.92 (95% CI range, 0.73 to 0.92) at optimal cutoffs ranging from 3 to 5 (Appendix H Figure 6, Appendix I Table 13).

**AUDIT.** Nine studies reported the test accuracy of the AUDIT to screen for unhealthy alcohol use (Appendix I Table 10). At a cutoff of ≥8, seven studies reported sensitivity ranging from 0.38 to 0.73 (95% CI range, 0.33 to 0.84) and specificity ranging from 0.89 to 0.97 (95% CI, 0.83 to 0.98) (Figure 5). A cutoff of ≥8 was optimal for only one subgroup in one study (males with mild depression). The optimal cutoffs ranged from ≥3 to ≥11, with sensitivity ranging from 0.68 to 0.90 (95% CI range, 0.43 to 0.96) and specificity ranging from 0.75 to 0.96 (95% CI range, 0.63 to 0.98) (Figure 6). Eight studies had an optimal cutoff of ≥3 to 5 for all participants or certain subgroups. For five studies, the optimal cutoff differed between males and females, with a lower optimal cutoff for females than for males. Six studies used the AUDIT to screen for those exceeding limits, with sensitivity ranging from 0.64 to 0.89 (95% CI range, 0.52 to 0.93) and specificity ranging from 0.67 to 0.95 (95% CI range, 0.59 to 0.97) at the optimal cutoff (ranging...
Three studies recruiting U.S.-based primary care patients reported data on lower AUDIT cutoffs (≥3 to 5) for unhealthy use (Figure 7). At a cutoff of ≥3, two of the studies reported sensitivity of 0.86 (95% CI range, 0.77 to 0.91), with specificity ranging from 0.74 to 0.83 (95% CI range, 0.68 to 0.85). At a cutoff of ≥4, sensitivity ranged from 0.71 to 0.84 (95% CI range, 0.64 to 0.88) and specificity ranged from 0.77 to 0.90 (95% CI range, 0.73 to 0.91) across the three studies. At a cutoff of ≥5, sensitivity ranged from 0.64 to 0.71 (95% CI range, 0.57 to 0.77) and specificity ranged from 0.87 to 0.94 (95% CI range, 0.83 to 0.95).

ASSIST. No studies among general adults reported on test accuracy for using the ASSIST to screen for the full spectrum of unhealthy alcohol use.

**Alcohol Use Disorder**

**One- or two-item.** Four one- or two-item screening tests were used in seven studies to screen for AUD, with sensitivity ranging from 0.71 to 0.94 and specificity ranging from 0.60 to 0.91 (Figure 8, Appendix I Table 11). The question recommended by the NIAAA on heavy episodic drinking (5/4+ drinks) was used in six studies, with sensitivity at the optimal cutoffs ranging from 0.71 to 0.92 (95% CI range, 0.65 to 0.98) and specificity ranging from 0.60 to 0.91 (95% CI range, 0.55 to 0.95).

**AUDIT-C.** Six studies reported the test accuracy of the AUDIT-C to screen for AUD (Appendix I Table 11). In three studies reporting accuracy for a cutoff of ≥3 for females, sensitivity ranged from 0.78 to 0.87 (95% CI range, 0.74 to 0.92) and specificity ranged from 0.69 to 0.85 (95% CI range, 0.65 to 0.75) (Figure 9). In three studies reporting test accuracy for a cutoff of ≥4 for males, sensitivity ranged from 0.87 to 0.88 (95% CI range, 0.78 to 0.94) and specificity ranged from 0.63 to 0.75 (95% CI range, 0.62 to 0.80) (Figure 10). The optimal cutoff for six studies was ≥3 or ≥4; one study had an optimal cutoff of ≥5 for males. At the optimal cutoff, sensitivity ranged from 0.70 to 0.88 (95% CI range, 0.65 to 0.95) and specificity ranged from 0.70 to 0.85 (95% CI range, 0.66 to 0.87) (Figure 11).

**AUDIT.** Eight studies assessed test accuracy of the AUDIT to screen for AUD (Appendix I Table 11). At a cutoff of ≥8, six studies reported sensitivity ranging from 0.43 to 0.96 (95% CI range, 0.35 to 1.0) and specificity from 0.82 to 0.96 (95% CI range, 0.74 to 0.99) (Figure 12). Only one study had ≥8 as the optimal cutoff. The optimal cutoffs ranged from ≥5 to ≥10 (seven studies reported optimal cutoffs of ≥5-7), with sensitivity from 0.48 to 0.96 (95% CI range, 0.35 to 1.0) and specificity from 0.34 to 0.96 (95% CI range, 0.28 to 0.99) (Figure 13).

Two studies recruiting participants from United States primary care reported test accuracy at lower cutoffs (≥4 and ≥5) (Figure 7, Appendix I Table 11). At a cutoff of ≥4, sensitivity was 0.83 (95% CI, 0.76 to 0.88), with corresponding specificity of 0.67 (95% CI, 0.63 to 0.71). At a cutoff of ≥5, sensitivity was 0.72 (95% CI, 0.65 to 0.79) and 0.80 (95% CI, 0.73 to 0.86), with corresponding specificity of 0.79 (95% CI, 0.75 to 0.82) and 0.88 (95% CI, 0.86 to 0.90). In contrast, sensitivity was much lower in these studies using the cutoff of ≥8 (0.43...
ASSIST. One study\textsuperscript{115} reported the test accuracy of the ASSIST to screen for AUD (Appendix I Table 11). The optimal cutoff for females was ≥7, with sensitivity of 0.86 (95% CI, 0.42 to 0.97) and specificity of 0.83 (95% CI, 0.77 to 0.88). The optimal cutoff for males was ≥13, with sensitivity of 0.80 (95% CI, 0.64 to 0.91) and specificity of 0.95 (95% CI, 0.90 to 0.98).

Older Adults

Study and Population Characteristics

Three good-quality studies recruited older adults from the community, one in Finland (n=517)\textsuperscript{88} and one in the United States (n=8,666).\textsuperscript{100, 133} The U.S.-based study recruited all adults and presented their test accuracy results for an older adult subgroup.\textsuperscript{100, 133} In the Finnish study, the mean age was 69 years, half of the participants were female, and race/ethnicity and SES were not reported. Subgroup-specific population characteristics were not reported for the U.S.-based study.\textsuperscript{100, 133} These studies assessed the accuracy of the AUDIT, AUDIT-C, and several one- or two-item screeners to screen for unhealthy alcohol use,\textsuperscript{88, 100, 133} AUD,\textsuperscript{100, 133} and alcohol dependence.\textsuperscript{88} The timeline followback was the reference standard for the Finnish study, classifying 23 percent of participants with unhealthy alcohol use; the U.S.-based study\textsuperscript{100, 133} used a structured clinical interview. An additional study, conducted in Spain, assessed only the test accuracy of the AUDIT and AUDIT-C to screen older adults for exceeding recommended levels of alcohol intake\textsuperscript{107}.

Full Spectrum of Unhealthy Alcohol Use

One- or two-item. Two studies\textsuperscript{88, 100} reported test accuracy for a variety of one- or two-item screening questions, with sensitivity ranging from 0.64 to 0.97 (95% CI range, 0.61 to 0.99) and specificity ranging from 0.70 to 1.0 (95% CI range, 0.65 to 1.0) (Figure 1, Appendix I Table 15). The U.S.-based study reported test accuracy for the NIAAA-recommended question (5/4+ drinks) to assess heavy episodic drinking, with sensitivity of 0.64 (95% CI, 0.61 to 0.67) and specificity of 1.0 (95% CI, 1.0 to 1.0).\textsuperscript{100, 133}

AUDIT-C. At the optimal cutoff of ≥4 in the Finnish study, sensitivity was 0.94 (95% CI, 0.88 to 0.97) and specificity was 0.80 (95% CI, 0.76 to 0.84) (Figure 4, Appendix I Table 15).\textsuperscript{88} Two studies\textsuperscript{100, 107} reported test accuracy to detect those exceeding limits with sensitivity ranging from 0.93 to 10.0 (95% CI range, 0.91 to 1.0) and specificity ranging from 0.81 to 0.85 (95% CI range, 0.80 to 0.86) at optimal cutoff of ≥3 and ≥4 (Appendix H Figure 6, Appendix I Table 13).

AUDIT. The sensitivity and specificity at the cutoff of ≥8 was 0.48 (95% CI, 0.39 to 0.57) and 0.97 (95% CI, 0.95 to 0.98), respectively, in the Finnish study (Figure 5, Appendix I Table 14). The optimal cutoff was ≥5, with sensitivity of 0.86 (95% CI, 0.78 to 0.91) and specificity of 0.87 (95% CI, 0.83 to 0.90) (Figure 6). At the optimal cutoff of ≥8, one study\textsuperscript{107} reported a sensitivity of 0.67 (95% CI, 0.64 to 0.70) and specificity of 0.95 (95% CI, 0.95 to 0.96) to detect those exceeding limits (Appendix H Figure 7, Appendix I Table 13).
**ASSIST.** No studies among older adults reported on test accuracy for using the ASSIST to screen for the full spectrum of unhealthy alcohol use.

**CARET.** No studies among older adults reported on test accuracy for using the CARET to screen for the full spectrum of unhealthy alcohol use.

**Alcohol Use Disorder**

**One- or two-item.** No studies among older adults reported on test accuracy for using a one- or two-item screening test to screen for AUD.

**AUDIT-C.** The U.S.-based study reported the test accuracy of the AUDIT-C to screen for AUD among adults 65 years or older who had drunk alcohol in the previous year. At the optimal cutoff of ≥4, sensitivity was 0.76 (95% CI, 0.67 to 0.83) and specificity was 0.74 (95% CI, 0.72 to 0.75) (Figure 11, Appendix I Table 16).

**AUDIT.** No studies among older adults reported on test accuracy for using the AUDIT to screen for AUD.

**ASSIST.** No studies among older adults reported on test accuracy for using the ASSIST to screen for AUD.

**CARET.** No studies among older adults reported on test accuracy for using the CARET to screen for AUD.

**Pregnant Women**

Two fair-quality studies94, 129 and one good-quality study100 recruited pregnant women. Two studies were set in the United States, with one recruiting American Indian women (or women carrying American Indian babies) at a mean of 15 weeks’ gestation attending prenatal appointments94 and the other recruiting pregnant past-year drinkers from the community through a large epidemiologic survey.100 The third study was set in Argentina and recruited postpartum women within 48 hours of delivery.129 Mean age was 24129 and 2694 years in two studies; the third study did not report maternal age100. In one study, based on a structured interview and medical records, 53 percent of women used alcohol during their pregnancy.94 The other study used a structured interview to identify the target conditions, reporting 5.5 percent with AUD and 3.5 percent with alcohol dependence.100 The study in Argentina did not report prevalence.129

**Alcohol Use**

**One- or two-item.** The study in American Indian women reported the test accuracy of a quantity-frequency question to screen for any alcohol use during pregnancy (Appendix I Table 18). At the optimal cutoff, sensitivity was 0.77 (95% CI, 0.68 to 0.83) and specificity was 0.93 (95% CI, 0.86 to 0.96).94

**Other tools.** No studies among pregnant women reported on test accuracy for using the AUDIT-
C, AUDIT, ASSIST, TWEAK, or T-ACE to screen for alcohol use.

**Full Spectrum of Unhealthy Alcohol Use**

No studies among pregnant women reported on test accuracy for using any screening test to screen for unhealthy alcohol use.

**Alcohol Use Disorder**

*One- or two-item.* No studies among pregnant women reported on test accuracy for using a one- or two-item screening test to screen for AUD.

**AUDIT-C.** Two studies reported the test accuracy of the AUDIT-C to screen for alcohol use disorder.\(^{100, 129}\) At a cutoff of ≥3, also the optimal cutoff in both studies, sensitivity ranged from 0.90 to 0.96 (95% CI range, 0.69 to 0.99) and specificity ranged from 0.71 to 0.79 (95% CI range, 0.65 to 0.82) (*Appendix I Table 19*).

**AUDIT.** In one study at the optimal cutoff of ≥4, sensitivity was 0.87 (95% CI, 0.74 to 0.94) and specificity was 0.86 (95% CI, 0.83 to 0.89).\(^{129}\)

**T-ACE.** In one study at the optimal cutoff of ≥2, sensitivity was 0.96 (95% CI, 0.86 to 0.99) and specificity was 0.76 (95% CI, 0.72 to 0.79).\(^{129}\)

**TWEAK.** In one study at the optimal cutoff of ≥2, sensitivity was 0.96 (95% CI, 0.86 to 0.99) and specificity was 0.77 (95% CI, 0.73 to 0.80).\(^{129}\)

**ASSIST.** No studies among pregnant women reported on test accuracy for using the ASSIST to screen for AUD.

**Key Question 3. What Are the Harms of Screening for Unhealthy Alcohol Use in Adolescents and Adults, Including Pregnant Women?**

Hypothesized possible harms included stigma, labeling, discrimination, privacy concerns, and interference with patient provider relationship. In addition, there may be legal concerns for pregnant women in some states. We found no trials that examined the harms of screening for unhealthy alcohol use.
Key Question 4a. Do Counseling Interventions to Reduce Unhealthy Alcohol Use, With or Without Referral, Reduce Unhealthy Alcohol Use or Improve Other Risky Behaviors in Screen-Detected Persons?

Key Question 4b. Do Counseling Interventions to Reduce Unhealthy Alcohol Use, With or Without Referral, Reduce Morbidity or Mortality or Improve Other Health, Social, or Legal Outcomes in Screen-Detected Persons?

Key Question 5. What Are the Harms of Interventions to Reduce Unhealthy Alcohol Use in Screen-Detected Persons?

Included Trials

We included 68 trials (n=36,528) that addressed the impact of a counseling intervention on alcohol use or health, social, or legal outcomes among a screen-detected population (Table 7, Appendix I Table 21). Two of the trials targeted adolescents,142, 143 22 target college-aged or young adults,144-164 29 addressed general adult populations,165-191 4 focused on older adults,192-195 and 11 targeted pregnant196-204 or postpartum205, 206 women. Tables 8 and 9 summarize study and population characteristics for these trials. Most trials were conducted in the United States (41/68 [60%]) and in primary care settings (42/68 [62%]). We rated 10 of the trials as good quality142, 144, 150, 163, 164, 175, 176, 192, 195, 202 and the remaining were fair quality; 28 trials were excluded due to poor quality. Nineteen of the trials (28%) were included in the previous review.

All trials conducted outreach to potential participants with a request to complete a screening instrument, although some studies also allowed participants to self-identify or accepted referrals from medical providers or service agencies. Most trials were limited to participants who reported a prespecified level of alcohol use (most commonly: either more than 7 (female) or 14 (male) drinks per week on average, or drinking 4 (female) or 5 (male) or more drinks on a single occasion), or scored above a predetermined cutoff on a screening instrument such as the AUDIT. Two trials did not restrict participants based on alcohol use, but reported subgroup analyses among unhealthy users.142, 147 Four trials among young adults included everyone screened regardless of screening results, rather than limiting their sample to unhealthy users,153, 154, 158, 163 and did not report subgroup analyses among those who met criteria for unhealthy alcohol use. We included these studies because the average consumption was in the high-risk use range, indicating an alcohol use reduction intervention was appropriate for at least half the sample. For example, two of the trials targeting incoming freshmen (average age 18) reported baseline weekly alcohol use of 3.5153 and 7163 drinks per week, along with an average of one heavy use episode every 2 weeks153 or an average of 2.2 alcohol-related problems.163 All four of these trials’ interventions were very consistent with other trials’ interventions in this age group.
Interventions

Information about the interventions can be found in Table 10 and Appendix I Tables 22 and 23. Most interventions involved 1 to 2 sessions (90% involved 4 or fewer sessions), with a median of 30 minutes of contact time (88% involved 2 hours of contact or less). Almost all interventions involved at least general feedback, such as how the participant’s drinking fit with recommended limits and how to reduce alcohol use. Many, particularly those in primary care settings, used an SBIRT approach, consistent with those recommended by several health organizations (Table 3). The most commonly reported intervention element was the use of personalized normative feedback sessions, in which participants were shown how their alcohol use compares to others; this technique was used in over half of the included trials and almost all trials in younger adults. Motivational techniques were also common, particularly in combination with personalized normative feedback. The use of drinking diaries and action plans or alcohol use “prescriptions” was also common, particularly in trials of general and older adults. A few interventions also incorporated more extensive cognitive behavioral counseling in conjunction with personalized normative feedback. Most trials in adolescents and young adults involved one or two in-person or Web-based personalized normative feedback sessions in school or university settings. Interventions targeting adults other than college students (including pregnant and postpartum women) were more likely to have taken place in primary care settings, had multiple sessions, and involved the primary care team in some way; approximately one-third of the interventions were delivered by the primary care clinician in trials of general and older adult populations. Three trials (with 4 intervention arms) involved group-based interventions, and four used a stepped-care approach, where participants who did not reduce alcohol use after a brief intervention were graduated to more intensive interventions. Six trials (in 7 intervention arms) incorporated feedback on how an individual’s alcohol consumption was affecting their health, such as elevated liver enzymes, symptoms or medical conditions that could be exacerbated by alcohol use, and potentially dangerous alcohol use with prescribed medications.

Summary of Results

Alcohol Use and Other Risky Behaviors (KQ4a)

The most commonly reported alcohol use outcome was drinks per week, which was reported in 45 of the included trials. On average, intervention groups reduced their drinking by 1.6 drinks per week more than control groups after 6 to 12 months, among 32 trials (in 37 analysis groups) that could be included in the meta-analysis (weight mean difference [WMD] between groups in change from baseline -1.59 [95% CI, -2.15 to -1.03], k=37, n=15,974, I²=63%, Figure 14, Table 11). This included only one trial in adolescents, with separate entries for moderate and high-risk users, so is primarily relevant to adult unhealthy alcohol users. Baseline use levels were highly variable, with trial baseline averages ranging from 3.8 to 59.3 drinks per week across all populations, and larger effects were typically seen with larger baseline use levels. The average drinking rate in the intervention groups changed from 20.5 drinks per week at baseline to 15.6 drinks per week at followup. In the control groups, the average drinking rate was 20.1 at baseline.
and 17.4 at followup. Excluding trials in adolescents and young adults, whose drinking pattern was generally typified by heavy use episodes rather than daily heavy drinking, the average drinks per week in adult populations changed from 26.0 at baseline to 19.1 at followup in the intervention groups and 25.6 at baseline to 21.6 in the control groups. Based on average baseline drinking levels and average change in drinks per week, there was a median reduction of 24 percent from baseline drinking levels after 6 to 12 months (interquartile range [IQR], 13% to 32%) in intervention participants, compared with a 16% reduction in the control group (IQR, 3% to 21%). Within-study variability in change was very large, with some participants showing large changes and others none, or even increasing their alcohol use, based on study-reported standard deviations.

A small-studies effect was identified for drinks per week (Egger’s test bias coefficient = -1.04, p=0.031, Figure 19), meaning that publication bias is a risk in this body of evidence, and is discussed more below, under “Heterogeneity in effect size.” Trials that could not be included in the meta-analysis generally showed effects of a similar size or slightly smaller, favoring the intervention group (e.g., between-group differences in change ranging from 0.9 to 1.8, or post-test differences of 2.3 drinks/week, or 10% to 20% relative reductions in use). The effects remained statistically significant when limited to trials conducted in primary care settings (WMD = -2.38 [95% CI, -3.44 to -1.33], k=21, I²=70%), in the United States (WMD = -1.27 [95% CI, -1.91 to -0.62], k=18, I²=64%), and in U.S.-based primary care settings (WMD = -1.75 [95% CI, -2.88 to -0.61], k=9, I²=77%) (Figure 15). Results remained statistically significant when the more conservative REML model was used for pooling (data not shown). Among trials conducted in primary care settings, pooled effects were very similar between interventions that did and did not involve the primary care team (Figure 15).

For trials with multiple followup assessments, effects were typically maintained between 6 and 12 months of followup; however, in several trials of young adults the statistical significance disappeared between 6 and 12 months. Across all populations, four trials found that treatment benefits were maintained through 24157, 160, 193 to 48175 months, but the effect disappeared between 12 and 48 months in another.182 Two other trials reported no group differences at 24179 and 36165 months of followup, but interim assessments were either not conducted or had unacceptably high attrition and were not abstracted, so it is unknown whether these interventions were effective in the short term.

We also found a pooled 40 percent reduction in the odds of participants still exceeding recommended drinking limits at followup (odds ratio [OR] = 0.60 [95% CI, 0.53 to 0.67], k=16, n=9,760, I²=24%, Figure 16, Table 11), although this outcome was reported in only 24 percent (16/68) of the included studies. Between 15 percent and 76 percent of participants exceeded recommended drinking limits at followup in the intervention groups, compared with 29 percent to 82 percent in the control groups. Similarly, there was a 33 percent reduction in the pooled odds of reporting an episode of heavy use (OR = 0.67 [95% CI, 0.58 to 0.77], k=14, n=8,108, I²=24%, Figure 17, Table 11), which was also relatively sparsely reported. Small-studies effects were not detected for either of these outcomes. The nine trials in pregnant women were most likely to report the odds of abstinence, rather than the aforementioned outcomes, which was doubled in the intervention groups, compared with control groups (pooled OR = 2.26 [95% CI, 1.43 to 3.56], k=5, n=796, I²=0%, Figure 18, Table 11) Other alcohol use outcomes were very
sparsely reported and generally showed very small statistically nonsignificant group differences.

Few changes in other behavioral outcomes were noted, such as in drug use, sex after alcohol use, and seeking help for unhealthy alcohol use, and were only rarely reported. One trial in a general adult population found a reduction in self-reported drinking and driving, but two did not, in younger and older adults. This trial in older adults reported that participants reduced the likelihood of using alcohol in the face of symptoms or comorbidities that could be exacerbated by alcohol, and with medication that could interact negatively with alcohol.

Among trials reporting drinks per week, several reported effects separately for males and females, or were entirely limited to males or females. Meta-analyses limited to men only and women only showed very similar between-group effects (WMD=-2.79 [95% CI, -4.10 to -1.49], k=11, I²=45; and -2.81 [95% CI, -4.45 to -1.17], k=9, I²=56 for men and women, respectively, data not shown). Among these trials, however, one found a substantially larger effect for men and two others showed smaller statistically nonsignificant differences favoring men but none of these trials reported the statistical significance of treatment-by-sex interactions. Four other trials reported testing the interaction between treatment effect and sex for an alcohol use outcome, with mixed results: three trials found larger relative treatment effects in women, and one reported no interaction effect. Further, results of trials with intervention tailored women was very limited, aside from those that targeted pregnant and postpartum women, and, with one exception, did not demonstrate superior effects.

Across a variety of alcohol use outcomes, a few studies explored differential effects by subgroups other than sex, including baseline drinking severity, readiness to change, drinking pattern, race, socioeconomic characteristics, and the presence of mental health comorbidities. Several trials found larger effects in patients with heavier baseline use on at least one outcome, although most did not report interaction tests. Few trials found differences in other subgroups, and none of the differences that were found were replicated. Since subgroup effects were reported only rarely, there is a risk that statistically significant results were preferentially published, so reported results may exaggerate subgroup differences in intervention benefit.

**Heterogeneity in Effect Size**

The effect size for our primary outcome, drinks per week, was larger in the subset of trials that had been included in the previous review (WMD=-2.83 [95% CI, -3.89 to -1.76], k=15, I²=68%) than those that were newly included (WMD=-0.77 [95% CI, -1.24 to -0.30], k=22, I²=28). Exploratory analyses indicated that several factors were associated with effect size and likely explained the difference between the effects in studies in the current and previous reviews: population (young adults vs. adults of other ages), setting (primary care vs. other), study n, baseline alcohol use, and year of publication. However, these factors were not independent of each other, and we were unable to determine which of these had a causal association with effect size.

Across all studies included in the meta-analysis for drinks per week (30 trials in adults of varying...
ages, including 1 in postpartum women, and 1 in adolescents), a statistically significant small-studies bias was detected \((p=0.031, \text{Figure 19})\). Smaller trials were more likely to have been published over 10 years ago and to have been among heavier drinkers. The median sample size in studies published in 2007 or later was roughly twice as large (median n analyzed=360, range 90 to 1488) as those published before 2007 (median n analyzed=158, range 61 to 774). Similarly, baseline drinks per week in trials published since 2007 (median=10, range 4 to 54) were less than half of those in older trials (median=22, range 11 to 64). \text{Figure 20} provides a visual display of the association between effect size and baseline alcohol use, showing the distribution of studies by baseline drinks per week in the control group by publication year. The size of the marker is weighted by the mean difference between groups in change from baseline, so trials with larger between-group differences have larger markers. The scatter plot shows that larger effects generally appear on the upper half of the figure (higher baseline drinks per week) and on the left (earlier publication year).

Older trials were also primarily conducted in general adult populations in primary care settings, while many of the newer trials were conducted in young adults in college settings, with baseline use levels that were considerably lower than in trials targeting general adult populations. Followup analyses found that the pooled effects were smaller, but still statistically significant, when limited to trials published in 2007 or later, with an average reduction of 1.1 drinks per week (\text{Figure 15}) and a 35 percent reduction in the odds of exceeding recommended drinking limits \((OR=0.65 [95\% CI, 0.56 to 0.76], k=8, n=6,569, I^2=23\%, \text{data not shown})\). This effect is not entirely due to the greater proportion of trials in young adults in the recent literature: when comparing effects between older and newer studies excluding the trials in young adults, effects were still larger in the older literature, but differences were less pronounced \((e.g., -1.59 \text{drinks per week in more recent literature vs. } -3.6 \text{drinks per week in older literature}, \text{Figure 15})\).

We did not find any treatment elements that were clearly associated with effect size \((e.g., \text{multisession vs. single-session contact, direct personal contact vs. computer or mail-only contact, estimated contact minutes, use of personalized normative feedback vs. not, use of motivational techniques vs. not, whether the primary care provider delivered the counseling vs. not}) among trials conducted in primary care). The lack of association with treatment elements held up even within baseline alcohol use strata \((\leq 14 \text{drinks/week}; >14 \text{to 28 drinks/week}, >28 \text{drinks/week}).\) However, among the trials of general and older adults there was a near-statistically significant effect showing larger effects with multiple vs. single contact interventions \((p=0.07)\), but this was not the case for trials limited to young adults \((p=0.61)\). Effect size was not influenced by study quality \((\text{fair vs. good}), \text{loss to followup, whether the trials targeted economically disadvantaged persons, or whether the trial included more than 50 percent racial and ethnic minority persons.}\)

**Health, Social, and Legal Outcomes (KQ4b)**

The most commonly reported health outcome was alcohol-related problems or consequences, measured using a variety of instruments. A pooled analysis showed a statistically significant, but very small, standardized mean difference in change between groups of \(-0.04 (95\% \text{CI, } -0.09 \text{ to } -0.01, k=18, I^2=3\%)\). The effect size \((\text{Hedge’s } g)\) can be interpreted as a Cohen’s D, where a small effect is typically considered to be 0.20 to 0.50.\textsuperscript{208} Mortality was reported in eight trials, primarily as part of the description of the participant retention. The pooled effect was not
statistically significant (OR=0.64 [95% CI, 0.34 to 1.19], k=9, n=4533, I²=0%, Figure 21), and also likely represents an overestimate of the true effect, since many trials that did not report deaths likely had no deaths, particularly those in young adults. Trials were not powered for this outcome and many had very few events, resulting in imprecise results. Only one trial, the Trial for Early Alcohol Treatment (TrEAT) trial, described ascertainment methods.\textsuperscript{175} This trial conducted a careful assessment of health outcomes through 4 years, based on self-report as well as electronic medical records, and databases from the government Crime Information Bureau, Department of Transportation, and Vital Statistics records. This trial found a statistically nonsignificant reduction in mortality at 4 years, with 0.8 percent (3/392) of intervention participants dying compared with 1.8 percent (7/382) of control participants. The difference in mortality between groups was statistically significant at 3 years of followup, when there had been only one death among intervention participants but seven among controls. The trial did not report whether any of these were related to alcohol use; however, two deaths in the control group were due to car accidents. Other causes of death were coronary artery disease and respiratory failure (in the control group), and suicide and myocardial infarction (in the intervention group).

The TrEAT trial also reported statistically significant reductions in days of hospitalization (420 in the intervention vs. 664 in the control group) and controlled substance or liquor violations (2 in the intervention vs. 11 in the control group) at 4 years of followup. In addition, they reported statistically nonsignificantly fewer ED visits (302 in intervention vs. 376 in the control group) and motor vehicle crashes with nonfatal injuries (20 in intervention vs. 31 in the control group) after 4 years. Other trials reported a wide variety of health outcomes, generally at 6 to 12 months of followup, with few findings of benefit for intervention over control groups.

**Harms (KQ5)**

Few studies reported on harms, and none identified any increased risk of harms with the included interventions. Further, no pattern of unexpected paradoxical increases in alcohol use was noted with these interventions.

**Detailed Results, by Subpopulation**

**Adolescents**

**Study, Population, and Intervention Characteristics**

Two trials targeted adolescents (n=1,160), one fair quality\textsuperscript{143} and one good quality,\textsuperscript{142} both published since the previous review. Both trials only reported results by subgroup, one by gender\textsuperscript{143} and the other by baseline severity.\textsuperscript{142} Retention was high in both trials, with 98 percent\textsuperscript{143} and 93 percent\textsuperscript{142} retention at 6 months of followup.

The first trial (n=119) involved a 20-minute counseling session for 14- to 18-year-olds attending primary care visits at either a large, urban, academic medical center or a public health clinic in the southeastern United States.\textsuperscript{143} This intervention used a motivational enhancement approach...
that also included personalized normative feedback and discussion of alcohol use in their peer network. Youth in this study were age 16.4 on average; 71 percent were female and 84 percent were black. Youth were eligible if they scored 2 or 3 on the CRAFFT with respect to alcohol or marijuana use, indicating they were at risk for a substance use disorder.

The other trial (n=469, among relevant subgroup) involved a single Web-based personalized normative feedback session among Swiss high school students (ages 16 to 19) followed by text messages tailored to the students’ baseline risk level. Average age in this trial was 16.8, 53 percent were female, and race/ethnicity was not reported. The trial included all students, regardless of alcohol use level, but reported results separately for those with and without unhealthy use. We limited our inclusion to the subgroup with unhealthy alcohol use, which was defined as one or more episodes of heavy use in the previous 30 days or more than 14 (males) or 7 (females) drinks consumed in a typical week. This group was further divided into two subgroups, with results only reported separately: those with more than two heavy use episodes in the previous 30 days (“high risk”), and those with one or two heavy use episodes (“moderate risk”).

**Alcohol Use and Other Risky Behaviors (KQ4a)**

Both trials found beneficial effects in one of two subgroups reported, and neither reported overall effects for the subgroups combined.

The U.S.-based study targeting alcohol and drug use found a statistically significant treatment-by-sex interaction and only reported results by sex, with beneficial effects seen only for males. Alcohol use during the previous 30 days decreased among males in the intervention group (from 0.52 to 0.25 on a scale of 0–7) and increased among males in the control group (0.50 to 0.81) over 6 months (Cohen’s d = 0.50, p<0.05). For females, alcohol use was slightly higher at baseline in the intervention group (1.19 vs. 0.69 in the control group), but both groups averaged around 0.8 at 6 months of followup (Cohen’s d not reported, p>0.05). The scale used for this study was: 0=0 days, 1=1–2 days, 2=was not reported, 3=3–5 days, 4=6–9 days, 5=10–19 days, 6=20–29 days, and 7=all 30 days.

The Swiss study of high school students found beneficial results only for the high-risk students, i.e., those reporting more than two episodes of heavy use in the previous month. Among these students, the number of drinks per week and heavy use episodes in the previous 30 days had declined by 7.95 drinks and 1.48 episodes at 6 months of followup, respectively, in the intervention group, compared with reductions in the control group of 3.54 drinks and 0.86 episodes. The reduction in heavy use episodes was statistically significant; drinks per week was not statistically significant in their adjusted model, although the unadjusted result shown in the Forest Plot was statistically significant (Figure 14). Reductions were smaller and between-group differences were not statistically significant for the moderate risk group: in the intervention and control groups, drinks per week declined by 0.94 and 1.26, respectively, and heavy use episodes declined by 0.05 and 0.06.
Health, Social, and Legal Outcomes (KQ4b)

Neither study reported health, social, or legal outcomes.

Harms (KQ5)

Neither study reported on harms related to the intervention.

Young Adults

Study, Population, and Intervention Characteristics

We identified 22 trials that targeted young adults (n=14,214). Most (20/22) of the trials in younger adults were conducted in university settings, including the four primary care-based trials,148, 150, 151, 162 which were conducted in university health clinics. Two-thirds (15/22) were conducted in the United States, and the remaining were in Europe, Canada, Australia, and New Zealand. Four trials were rated as good quality,144, 150, 163, 164 and median retention across all trials was 84 percent (range 65 to 90) at 6 to 12 months of followup. The average participant age was 19.8, 51.5 percent participants were female, and most participants were white or Asian. Most trials of young adults selected participants based on the presence of heavy use episodes, typically defined as four or more drinks on one occasion for females and five or more drinks on one occasion for males. Almost 90 percent (34/36) of the interventions in these trials involved personalized normative feedback, usually delivered in one or two brief sessions, with over half delivered via computer or the Web and no or minimal direct interaction with study staff. One study (with two treatment arms) involved parents via mailed materials.163 Four of these trials were included in the previous review.148, 150, 162, 209

Alcohol Use and Other Risky Behaviors (KQ4a)

Young adults reduced their alcohol use by an average of 0.87 drinks per week (WMD= -0.86 [95% CI, -1.29 to -0.43], k=14, n=6,935, I²=11%, Figure 14). Results were similar when we dropped the trials that had no alcohol use restrictions, and therefore included some participants who were not unhealthy alcohol users (WMD=-0.89 [95% CI, -1.52 to -0.26], k=12, n=4,864, I²=24%). The five trials that could not be included in the meta-analysis showed similarly modest effects.150-153, 160 with between-group differences in change ranging from -0.9 to -1.8, and three trials reporting 10 and 20 percent reductions in risk negative binomial models. Interestingly, one additional primary care-based trial targeting a general adult population, published in 1997, reported subgroup analyses for younger adults (ages 18 to 30), and found substantially larger effects: intervention participants reported a reduction of 4.1 drinks per week (95% CI, -7.1 to -1.1) more than control group participants at 12 months of followup.175 Baseline use in the young adult subgroup of this study was 18 drinks per week, which is an average of 7 more drinks per week than in trials limited to young adults.

Of the six trials reporting results at both 6 and 12 months, four found that benefits at 6 months
were no longer statistically significant at 12 months for at least one intervention group. Only two trials reported outcomes beyond 12 months, and both found that benefits were maintained through 24 months, although only for the most intensive and specifically tailored intervention group in one of these trials. A number of trials included multiple intervention groups, and we used the group we judged to be most intensive or comprehensive; other intervention groups showed comparable or smaller effects, on drinks per week and other alcohol use outcomes. One trial in a general adult population found that 12-month benefits for drinks per week were maintained through 24 months in a subgroup analysis of younger adults ages 18 to 30, but were smaller and no longer statistically significant at 36 months of followup.

Most trials in young adults recruited participants with episodes of heavy use; however, this outcome did not show a benefit of treatment in this population, either as number of heavy use episodes per week (WMD = -0.06 [95% CI, -0.16 to 0.05], k=7, n=2,968, I²=33%, data not shown), or as the proportion with heavy use episodes in the previous month (OR=0.81 in each of 2 trials, neither statistically significant, Figure 17). However, the trial targeting a general adult population that reported subgroup analyses for younger adults did find larger effects for heavy use episodes, as they did for drinks per week: intervention participants reported a reduction of 2.0 more heavy use episodes per month (95% CI, -3.1 to -0.9) than control group participants after 1 year. Among trials limited to young adults, both trials that reported the proportion exceeding recommended limits showed improvements over control: reductions in the odds of exceeding limits were 35 percent (95% CI, 46% to 92%) and 26 percent (95% CI, 60% to 91%). Pooled effects were not statistically significant for drinks per drinking day (WMD= -0.40 [95% CI, -0.90 to 0.10], k=4, n=1,026, I²=56%, data not shown).

Four trials in young adults were conducted in primary care settings, and three of these had positive results across multiple drinking outcomes after 6 months, but group differences were not maintained at 12 months. The fourth trial showed statistically nonsignificant 10 to 20 percent reductions in risk across three alcohol use outcomes, assessed only at 6 months of followup.

One trial each reported no between-group differences in self-reported drinking and driving or in marijuana-related consequences.

**Health, Social, and Legal Outcomes (KQ4b)**

Thirteen trials reported results for alcohol-related problems or consequences, and the pooled estimate showed a small but statistically significant standardized difference in favor of the intervention groups (standardized mean difference [Hedge’s g]= -0.06 [95% CI, -0.11 to -0.01], I²=0%, Figure 22). This is a very small effect, with even the upper confidence interval falling well below what would usually be considered a small effect size. The most commonly used instrument was the Rutgers Alcohol Problems Index (RAPI), a 23-item instrument asking how many times respondents had experienced the list of problems due to alcohol use, such as not being able to do homework or study for a test, getting into fights, neglecting responsibilities, and finding yourself in a place you could not remember getting to. It also includes some items specifically about alcohol use (feel that you had a problem with alcohol, want to stop drinking...
but can’t). Included trials used different versions, with response category values of 0–1, 0–3, and 0–4. Three trials also reported scales measuring academic impacts, with one reporting greater improvements in the intervention groups (negative binomial RR=0.8, p<0.05 at 6 and 12 months of followup)\(^{151}\); the other two did not find statistically significant group differences (negative binomial RR=0.9, p=0.87\(^{152}\) and median Academic Role Expectations and Alcohol Scale (AREAS) score 4 (out of 35) in the control group versus 2 in the intervention group, p=0.06,\(^{150}\) both at 6 months of followup). Two other trials found no between-group differences in risk-taking behavior\(^{162}\) or a composite health-care utilization outcome that included inpatient, emergency department, urgent care, and detox services.\(^{148}\)

### Harms (KQ5)

Three trials reported no adverse effects in both groups.\(^{154, 156, 160}\) Two trials had point estimates that favored the control group by less than one drink per week, however these effects appeared consistent with true, underlying effect being scattered around a small beneficial effect on average, and individual study results falling a small distance on either side of the average effect\(^{145, 146}\). Thus, no pattern of paradoxical effects was identified that would indicate that these interventions could be harmful in young adults.

### General Adult Populations

#### Study, Population, and Intervention Characteristics

We identified 29 trials (n=16,944) that targeted adults of all ages. Most trials in general adult populations were conducted in primary care settings (24/29 [83%]). Ten trials altogether were conducted in the United States; the remaining studies were conducted in Canada, Australia, and Europe. Three trials were rated as good quality,\(^{175, 176, 202}\) and across all trials the median retention was 77 percent (range 59 to 96) at 6 to 24 months of followup. The average age was 44.7; 42 percent of participants were female. Among trials conducted in the United States, where race/ethnicity was most consistently reported, 76 percent of participants were white, 19 percent were black, and 17 percent were Hispanic; four included majority nonwhite samples.\(^{167, 185, 189, 210}\) Five of the trials had a substantial proportion of participants who were socioeconomically disadvantaged (i.e., >50% of participants were uninsured or on Medicaid, on public assistance, unemployed, or had an annual income of <$15,000).\(^{167, 185, 189, 191, 202}\) Almost half (18/38) of the interventions in these studies included personalized normative feedback, and three trials (with four intervention arms) also included personalized feedback about health effects related to their alcohol use.\(^{167, 177, 190}\) Most of these interventions took place in person and 63 percent (24/36) involved the participant’s primary care team; the primary care clinician delivered most or all of the intervention in 34 percent (13/36) of the interventions. Eleven of these trials were included in the previous review.\(^{166, 172, 175, 181-183, 185, 187, 188, 190, 202}\)

#### Alcohol Use and Other Risky Behaviors (KQ4a)

Drinks per week totals were reduced in general adult populations by an average of three drinks per week (WMD= -2.51 [95% CI, -3.81 to -1.21], k=18, n=7662, I\(^2\)=70%, Figure 14). Five of
the six trials that reported this outcome but could not be included in the meta-analysis did not show statistically significant differences, with effects across all six studies ranging from -1.3 to -3.1 with greater reduction in drinks per week in the intervention group, to fewer drinks per week at followup in the intervention group. Effects were generally consistent with respect to statistical significance across multiple intervention groups or attenuated with less intensive approaches, although one trial did find larger effects at 12 months (but not 6 months) of followup with a single 10- to 15-minute advice session than with the more intensive arm that offered a 30- to 40-minute motivational enhancement intervention followed by two brief booster sessions. Two trials reported outcomes for drinks per week beyond 12 months; one found that benefits dropped off at 24 months but the other study maintained a difference of 0.3 greater reduction in drinks per week in the intervention group than the control group through 48 months (from -0.4 drinks/week difference at 12 months of followup).

The odds of exceeding recommended limits were reduced by 44 percent (OR= 0.56 [95% CI, 0.49 to 0.65], k=11, n=4964, I²=14%, Figure 16). Heavy use episodes were reduced by 35 percent (OR=0.65 [95% CI, 0.53 to 0.81], k=7, n=3683, I²=44%, Figure 17). Three trials reported other behavioral outcomes: one reported lower self-reported drinking and driving (20% in the IG vs. 35% in the CG reported that in the previous month they had driven after more than two drinks, OR=0.46 [95% CI, 0.27 to 0.76]), one found no between-group differences for having sex after drinking among patients attending a sexual health clinic (OR=0.79 [95% CI, 0.33 to 1.75]), and the third found no differences in the number of days participants had used drugs (mean difference in change=-4.5 [95% CI, -24 to 15]).

A few trials in general adult populations reported effects of subgroup analyses. One trial reported no interactions with age, education, marital status, or employment status, but only examined these interactions in males. Another trial reported a treatment benefit only in those drinking above recommended limits but without an AUD or heavy use episodes in the previous month, while no clear benefit was found in those with AUD or heavy use episodes at baseline. A third trial found no differences in treatment effect in older adults versus younger and middle-aged adults.

**Health, Social, and Legal Outcomes (KQ4b)**

Five trials reported mortality outcomes, usually as part of a description of the participant flow, and none found an effect on mortality. This included the TrEAT trial with 4 years of followup and well-reported ascertainment methods that found 0.8 percent and 1.8 percent of intervention and control participants had died, respectively. As covered in the overall summary of results above, at 4 years of followup this trial found reductions in days hospitalized (420 in the intervention vs. 664 in the control group) and controlled substance or liquor violations (2 in the intervention vs. 11 in the control group), as well as statistically nonsignificant differences in emergency department (ED) visits (302 in intervention vs. 376 in control group) and motor vehicle crashes with nonfatal injuries (20 in intervention vs 31 in control group). Aside from the TrEAT trial, six other trials reported various self-rating medical or physical health items or scales, and between-group differences favoring the intervention group were found in only one study, on the Medical subscale of the Addictions Severity Index (detailed data
The others reported small effects that did not consistently favor the intervention groups for these outcomes. Similarly, one trial reported quality-adjusted life years, five reported various mental health-related scale scores, and none found group differences at 6 to 12 months of followup. Other outcomes that were reported (excluding the TrEAT trial) almost always showed no clinically or statistically important differences between groups, and included general consequences scales, liver enzymes, blood pressure, hospitalizations, and accidents.

**Harms (KQ5)**

One trial reported no adverse events in any arms of the trial. Although no pattern of paradoxical effects was identified that would indicate that these interventions could be harmful in general adult populations, one trial did report that control group participants were more likely than intervention participants to be below that AUDIT cutoff of 8, indicating nonproblematic levels of alcohol use. However, in this trial the point estimates favored the intervention group for the related outcomes of exceeding recommended limits and heavy use episodes, suggesting no actual harm.

**Older Adults**

**Study, Population, and Intervention Characteristics**

Four trials focused on older adults (n=2,504), with minimum ages ranging from 55 to 65 (average age, 68.5), all in primary care settings; three were conducted in the United States and one in Great Britain. Two trials were rated as good quality, and retention across all four trials ranged from 83 to 92 percent. Thirty percent of the participants were female and there was minimal representation of race/ethnic minority or low-SES patients. All of these interventions included multiple contacts, combining in-person and phone contacts. One used a stepped-care approach and had repeat visits only if the participant hadn’t changed their alcohol use at a 4-week followup call. Two of these trials were included in the previous review.

**Alcohol Use and Other Risky Behaviors (KQ4a)**

Three of the trials in older adults reported drinks per week at 12 months of followup, all showing greater reductions in the intervention groups (Figure 13). Differences in change between groups ranged from -2.2 (95% CI NR, p<0.01) (not included in the meta-analysis) to -5.3 (95% CI, -8.5 to -2.1) from baseline use levels of 14 to 17 drinks per week. Beneficial effects were maintained through 24 months in one trial, at which point intervention group participants had reduced their drinking by an average of three more drinks per week than control group participants (p<0.001). The same three trials also reported reductions in the proportion exceeding recommended drinking limits after 12 months, with odds ratios ranging from 0.33 (95% CI, 0.15 to 0.73) to 0.75 (95% CI, 0.42 to 1.36) (Figure 16). One trial also reported a greater reduction in the heavy use episodes per month at 12 months (mean difference in change=-3.1 [95% CI, -5.6 to -0.6], p<0.001), but the effect deteriorated and was not maintained at 24 months. Between-group differences in change were not seen for the AUDIT-C or the
CARET. One trial reported that participants reduced the likelihood of using alcohol in the face of symptoms (OR=0.60 [95% CI, 0.46 to 0.80]) or comorbidities (OR=0.72 [95% CI, 0.53 to 0.96]) that could be exacerbated by alcohol, and with medication that could interact negatively with alcohol (OR=0.66 [95% CI, 0.51 to 0.85]). This trial did not find group differences in driving within 2 hours of having three or more drinks, which was reported by 11 percent and 16 percent (p=0.27) at 6 months in the IG and CG, respectively, and 14 percent and 17 percent at 12 months of followup (p=0.06).

Health, Social, and Legal Outcomes (KQ4b)

One trial reported a reduction in ED visits (OR=0.56 [95% CI, 0.33 to 0.96]) and in depressive symptoms (mean difference at post-test 0.14 on a 5-point scale, p<0.05). Two trials found no statistically significant group differences in change on the SF-36 mental and physical component scores. Across both scales and two different time points for each study, between-group differences in change ranged from 0.4 (95% CI, -0.4 to 1.2), favoring the control group, to -1.2 (95% CI, -3.1 to 0.6), favoring the intervention group, with baseline scores ranging from 44 to 51 on a 100-point scale.

Harms (KQ5)

One trial reported no adverse events in either arm of their trial. No pattern of paradoxical effects was identified that would indicate that these interventions could be harmful in general adult populations.

Pregnant and Postpartum Women

Study, Population, and Intervention Characteristics

We identified 11 fair-quality trials (n=2278) that evaluated the effectiveness of interventions to reduce alcohol use among pregnant and postpartum women. One trial was conducted in The Netherlands and the other 10 were conducted in the United States. The trials targeting pregnant women took place in outpatient obstetric settings, usually at prenatal visits during the first or second trimester. The trials in postpartum women recruited in the hospital postdelivery and at a 6-week postnatal visit. Median retention was 81 percent (range 63% to 100%) after 1 to 12 months; most of the trials followed the women for 6 months or less. Among the studies in the United States, approximately half of participants were white, 31 percent were black, and 15 percent were Hispanic. Seven of these trials included a substantial number of socioeconomically disadvantaged women. The interventions in these populations involved one to four sessions, which were generally described as “brief” or 10 to 20 minutes in length, for total contact time ranging from an estimated 10 to 80 minutes. Six used motivational techniques and another used the Transtheoretical Model framework, suggesting use of different motivational techniques for participants in different stages of change with regard to alcohol use. Three described the use of cognitive-behavioral techniques. Three of the interventions were delivered via computer or the Web, with minimal contact with study staff. Two of these trials were included in the previous
Alcohol Use and Other Risky Behaviors (KQ4a)

The most commonly reported outcome in trials targeting pregnant women was abstinence from alcohol. The pooled odds of abstaining from using alcohol during pregnancy was nearly doubled in the intervention groups, compared with control groups (OR=1.92 [95% CI, 1.19 to 3.09], k=5, n=796, I²=9%, Figure 18); however, the recall range was highly variable, ranging from 1 to 3 months. The percent of reported abstinence in the control groups ranged from 11 to 89 percent, while intervention groups ranged from 18 to 90 percent. However, the between-group difference in abstinence was statistically significant in only two of the five trials. Four trials reported drinks per drinking day, but none found differences and in many cases the mean change values in the two groups were with 0.2 of each other, with some results favoring the control groups. Similarly, no statistically significant (or potentially clinically important) differences were detected on other drinking outcomes, such as drinks per week, drinking days per week, percent of days used alcohol, and AUDIT score. In postpartum women, one trial (n=235) reported greater reduction in drinks per month (dropping from 34 to 20 drinks/month in the intervention group, compared with a change from 32 to 27 drinks/month in the control group) and heavy use episodes per month (dropping from 10 to 7 in the intervention group vs. 10 to 9 in the control group). In the other trial in postpartum women (n=123), although mean scores consistently favored the intervention group, post-test scores did not differ statistically on number of drinking days in the previous 3 months (15 and 22 in the intervention group and control group, respectively), drinks per week (6.4 and 8.7), or heavy use episodes per week (0.56 and 0.75).

Two trials of pregnant and postpartum women reported on subgroup effects. One trial in low-income pregnant women reported that treatment effects were larger in those who drank fewer than eight drinks per month (vs. ≥8 drinks/month), were African-American, and were teenagers, although they did not report whether they tested interaction terms. Another trial reported a greater treatment effect on birth length among those with higher (vs. lower) baseline alcohol consumptions, but no such effect for birthweight and drinks per drinking day.

Health, Social, and Legal Outcomes (KQ4b)

Two trials reported birthweight, finding the average to be 224 g higher in the intervention group of one trial (p<0.03) but no between-group different in the other trial. Trials also reported no differences in gestational age (detailed results NR), head circumference (detailed results NR), fetal mortality (OR=0.29 [95% CI, 0.03 to 2.62]), or live birth of >2500 g and no admission to neonatal intensive care (OR=3.30 [95% CI, 0.80 to 13.8]). One trial found no differences between groups on “basic psychological need satisfaction.” Neither of the trials in postpartum women reported health, social, or legal outcomes.

Harms (KQ5)

One trial in pregnant women reported no adverse events in either arm of the trial. No pattern
of paradoxical effects was identified that would indicate these interventions could be harmful in pregnant or postpartum women.
Chapter 4. Discussion

Unhealthy alcohol use has substantial and wide-ranging negative effects at the individual, family, and societal level. A summary of our findings is presented in Table 12, including our overall strength of evidence for each key question.

Summary of Evidence

We found no direct evidence that screening programs reduce unhealthy alcohol use or improve health, compared with usual care (without screening). Multiple screening instruments are available that can detect unhealthy alcohol use with reasonable accuracy, and that require 1 or 2 minutes to administer. For example, studies of adults found that the NIAAA-recommended single question (How many times in the past year have you had 5/4 [males/females] or more drinks in a day?) had sensitivity ranging from 0.73 to 0.88 and specificity from 0.74 to 1.0 for detecting unhealthy alcohol use. For the AUDIT-C, sensitivity was similar, but the range of reported specificity was wider. For the full AUDIT, range of sensitivity was wide (0.38 to 0.73) using the recommended cutoff of ≥8, but specificity was high (0.89 to 0.97). This pattern supports its use as a second step after an initial positive screen with either the single question or AUDIT-C, as is currently done in some health care systems, such as the Veterans Health Administration. If used as an initial screening test, data for the AUDIT from U.S.-based primary care settings suggests that lower cutoffs may be preferable (e.g., 3, 4, or 5) to provide a more optimal balance of sensitivity and specificity for detecting the full spectrum of unhealthy alcohol use. Given the low cost of followup questions after a positive screen to confirm the presence of unhealthy alcohol use and determine its extent (if present), clinicians may prioritize sensitivity over specificity, and may consider calibrating the optimal cutoff for their setting. Use of the USAUDIT and USAUDIT-C, designed to use the United States standard drink size and to return results consistent with NIAAA recommendations, may improve upon the performance of the standard AUDIT and AUDIT-C, though no studies have yet been published to confirm this improvement.

For adolescents, limited data were available on accuracy of any screening instrument for detecting the full spectrum of unhealthy alcohol use (one study with 225 participants), but multiple studies demonstrated good accuracy of one- or two-item questions and the AUDIT for detecting AUD. Despite the adequate test accuracy, the low prevalence of unhealthy alcohol use among adolescents, older adults, and pregnant women will result in low positive predictive values, less than 50 percent for all scenarios we modeled in these populations (Table 13). Among nonpregnant adults, the prevalence of unhealthy alcohol use is higher, resulting in fewer false positives. For example, the positive predictive value in general adult populations is estimated at 74 percent for identifying persons with heavy use episodes, at a sensitivity of 0.80 and specificity of 0.90.

Our results indicated that among adults who were identified through screening, counseling interventions to reduce unhealthy alcohol use led to reductions in alcohol use (by an average of 1.6 drinks/week), and reduced both the odds of exceeding recommended drinking limits (by
40%) and heavy use episodes (by 33%) at 6 to 12 months of followup (Table 12). Based on these findings, among adult unhealthy users, and assuming a control rate of 33 percent drinking within recommended limits at followup (the median of our included trials), such interventions would result in an absolute increase of 14 percent more participants drinking within recommended limits, meaning seven adults would need to be treated to get one drinking within recommended limits (number needed to treat [NNT]=7.2 [95% CI, 6.2 to 11.5]). For context, number need to treat with high-intensity counseling interventions to prevent one case of a biologically-confirmed sexually transmitted infection ranges from 16 to 69, across 3 levels of baseline risk. In pregnant women, interventions doubled the odds that women remain abstinent from alcohol during pregnancy (NNT= 6.0 [95% CI, 4.3 to 12.5], assuming a baseline rate of 62 percent of women being abstinent from alcohol). Intervention effects are likely similar for men and women, and there was no evidence to suggest that different race/ethnicity or socioeconomic subpopulations had lower likelihood of benefit. Evidence in adolescents was limited to two trials, with mixed results.

Very limited data suggested that benefits from alcohol use interventions can be maintained over 2 to 4 years, including both drinks per week and some health outcomes. However, several trials in younger adults found that beneficial effects appeared at 6 months, but were attenuated and no longer statistically significant at 12 months, suggesting that beneficial effects may deteriorate more quickly in younger adults.

While many trials reported health, social, legal, and related outcomes, no specific outcomes were widely reported. Eight trials reported mortality, finding that the interventions were associated with a 36 percent reduction in the odds of death (OR=0.64 [95% CI, 0.34 to 1.19]) but was not statistically significant. We found very limited information on harms of the included intervention, but the fact that most results favored the intervention groups across a wide range of outcomes, even though differences were not always statistically significant, suggests very low risk of harm. Several studies reported on the acceptability of their interventions to the participants, and generally reported positive to very positive ratings.146, 180, 199, 203, 206

**Comparison With the 2012 USPSTF Review**

The previous USPSTF review examined existing systematic reviews to address the question of screening test performance. The previous reviewers concluded that a single-question screener, the AUDIT-C, and the AUDIT appeared to be the best overall instruments for screening adults for the full spectrum of unhealthy alcohol use in primary care, with single-question screeners having reported sensitivities of 0.82 to 0.87 and specificities of 0.61 to 0.79. They further concluded that lower cut-points on the AUDIT than the standard ≥8 may provide a more optimal balance of sensitivity and specificity in U.S.-based primary care. We examined original studies rather than existing systematic reviews, so our evidence base is more directly applicable to United States primary care, and at least 60 percent of the studies included in our review were published after the search windows of the previous review’s evidence, so most of the included studies are new since the previous review. The ranges of sensitivities and specificities estimated by the previous review for adults are solidly in the range of the sensitivities and specificities seen in our review in studies of adults. Among the newly included evidence is 10 studies in
adolescents, who were not previously represented.

Among intervention trials included in our review, the pooled effect size was more than two drinks per week larger for trials that were included in the previous review \(^7^7\) than for trials that were not included in the previous review (Figure 15). Table 14 shows intervention trial results from the previous and current reviews side-by-side. While reductions in drinks per week were larger in the previous review, other drinking outcomes showed very similar results. One of the main differences between the two reviews is the inclusion of studies conducted outside of primary care settings in the current review, which resulted in the inclusion of a substantial number of studies in college settings. Differences in the results for drinks per week between the two reviews were likely due to this and other factors, including differences in the distribution of population age and severity, and possibly also to small studies effects or secular trends in treatment response over time. Differences between reviews in drinks per week were less pronounced within the general and older adult trials. For example, the average relative reduction in drinks per week in general adult populations was 3.6 in the previous review and 2.5 in the current review. Our estimated absolute increase of 14 percent more participants drinking within recommended limits based on the assumption described in the previous paragraph (and NNT=7.2) is also consistent with the 11 percent increase (NNT=9) reported in the previous review. Also consistent with the previous review was our finding of a fairly large but statistically nonsignificant association between interventions and reduced all-cause mortality, with a 36 percent reduction in the odds of death in the current review (OR=0.64 [95% CI, 0.34 to 1.19]), compared with a 48 percent reduction in the risk of death in the previous review (RR=0.52 [95% CI, 0.22 to 1.22]).

**Comparison With Other Reviews**

We found only one systematic review of test performance of a relevant screening tool that was published after the previous review, which confirmed the efficiency of the English-language AUDIT, AUDIT-C, and other abbreviated versions of the AUDIT, as well as other language-adapted versions.\(^{215}\) Other systematic reviews of interventions to reduce unhealthy alcohol use are largely consistent with our findings. For example, a series of systematic reviews of experimental and quasi-experimental studies in adolescents and young adults\(^{216-218}\) found relatively small but statistically significant effects in young adults (e.g., an estimated 0.8 fewer drinking days per month) that weakened with longer-term followup. A separate review in young adults reported a similar standardized effect size, which translated to reducing drinks per week from 13.7 at baseline to 12.5 at followup (standardized mean difference between groups=-0.14; 95% CI, -0.21 to -0.07).\(^{219}\) Systematic reviews of electronic screening and brief interventions among trials targeting all ages also found effect sizes consistent with ours,\(^{220, 221}\) such as a pooled greater reduction of 15 grams of ethanol per week (WMD= -14.91; 95% CI, -25.56 to -4.26) in intervention versus control groups after 6 to 11 months, and 7.5 grams per week at 12 months (WMD= -7.46; 95% CI, -25.34 to 10.43).\(^{220}\) Using a conversion factor of 14 grams of ethanol for one drink, this is similar to the effect found in young adults in our studies of just under one drink per week, measured at 6 to 12 months. While this review included studies from a wide range of countries and settings, five of the eight trials in their meta-analysis of 6- to 11-month outcomes were trials in young adults that were included in our review. Approximately half of the trials in
young adults in our review were electronically based interventions. The other review of electronic interventions found a similar effect size of roughly one drink per week.\textsuperscript{221} We did not find other recent systematic reviews of the benefits or harms of interventions in general adult populations.

**Other Evidence Related to Benefits and Harms of Screening**

Although no trials met our inclusion criteria for the key questions related to the benefits and harms of screening compared with no screening, we identified two trials that explored the population-level impact of alcohol screening programs. Control group participants were screened in both trials, so they did not meet the criterion for KQ1 of having an unscreened control group. These trials provided weak evidence for alcohol-use screening programs and suggest this could be a promising area for future research. Both trials screened for a number of risk factors for an outcome of interest (cancer\textsuperscript{222} and alcohol exposed pregnancy\textsuperscript{223}), including unhealthy alcohol use. After screening, patients in the intervention groups were provided with counseling targeted to risk factors identified by the screening. In both trials, results were reported for the full study sample, not only those who screened positive for unhealthy alcohol use. A trial of American Indian/Alaska Native women found a statistically nonsignificant reduction in the proportion at high risk for an alcohol-exposed pregnancy at followup (reduced from 36.4\% at baseline to 18.9\% in the intervention group, and 33.6\% to 22.1\% in the control group, \textit{p}=0.72, \textit{n}=263).\textsuperscript{223} The other trial, in Spanish primary care patients, found that after 18 months, the proportion meeting criteria for risky drinking fell from 10.1\% to 4.9\% in the intervention group, versus 10.0\% to 8.3\% in the control group (OR 0.50 [95\% CI, 0.35 to 0.72], \textit{p}<0.001, \textit{n}=3,031). Neither study reported on harms. Another study of a screening and motivational interview intervention was excluded due to high attrition (46\% lost to followup).\textsuperscript{224} This study in young women (mean age 18.2) presenting at youth health centers did not show group differences in alcohol use outcomes at 12-month followup, among those with high risk alcohol use at baseline.

**Contextual Information to Bound Intervention Effect Sizes Found in the Current Review**

Based primarily on data in nonobstetric adults, we identified several factors that were associated with reduction in drinks per week, such as sample size, publication year, baseline alcohol use, target age of the population, setting, and possibly contact time among trials of general and older adults. We were unable to determine which factors were most likely to have causal associations with drinks per week since they tended to cluster together: older studies tended to have smaller sample sizes, target heavier drinkers, have been conducted in primary care, target general adult populations, and have larger effects. Given the relatively larger effects in primary care settings, even if the overall reduction of 1.8 drinks per week is an overestimate due to small studies effects or secular changes in treatment responsiveness, it is likely a reasonably conservative lower-bound estimate of the true, current effect in primary settings, targeting the full spectrum of unhealthy alcohol use. And, our results could also underestimate the true effect, since the assessment and minimal interventions may have contributed to reduced drinking in control
groups. A systematic review concluded that answering questions about drinking in brief intervention trials seems to alter subsequent self-reported behavior, potentially generating bias (toward the null) by exposing nonintervention control groups to an integral component of the intervention. Indeed, many included trials showed drinks per week declining over time in the control group as well as the intervention group, particularly between baseline and the first followup.

Our results for mortality (OR=0.64 [95% CI, 0.34 to 1.19]) were consistent with the impact of reduced alcohol use on persons with alcohol use disorders in a systematic review of 16 studies among individuals with AUD at baseline. This review found that participants who reduced their drinking but did not attain abstinence had a 39 percent reduction in the odds of death compared with those who continued heavy drinking (OR=0.61 [95% CI, 0.39 to 0.94]). This supports the potential clinical importance of our mortality results, although caveats regarding potential reporting bias, lack of information about ascertainment, and imprecision in our evidence remain important.

The most commonly reported health outcome was alcohol-related problems or consequences. This outcome was frequently reported in young adults, typically using the RAPI. This may be an important outcome for young persons, as there is some evidence linking RAPI scores at age 18 to diagnosis of AUD seven years later. This study of twins who were concordant and discordant for both RAPI at age 18 and AUD at age 25 found a 10-fold increase in the odds of having a diagnosis per unit increase in the RAPI at age 18. Several of our included studies reported between-group differences in change in the range 0.4 to 1.5 units on the RAPI, favoring the intervention group, however the units varied across studies, hampering interpretation (i.e., some used the RAPI as a 23-point scale, others as a 69-point scales, and other variations). Also, two trials reported similar absolute changes but favoring the control group.

A few of our trials reported on emergency and inpatient health care utilization, with mixed results and generally limited power. Among studies that were not included in our review, one uncontrolled implementation study suggests the potential for benefit with large-scale implementation. This study of Medicaid patients at 33 clinics in Wisconsin found that screening and brief interventions for unhealthy alcohol use in these real-world settings reduced hospital days by 0.036 days per member per month (PMPM), although the impact on inpatient admissions (-0.001 admissions PMPM) and emergency department days (-0.004 days PMPM) were not statistically significant.

Importance of Specific Intervention Components

Aside from a nearly-statistically significant effect of single vs. multiple contacts among general and older adults, we did not find intervention characteristics that were clearly associated with drinks per week, in-person versus Web-only contact, or use of motivational techniques, personalized normative feedback, or cognitive-behavioral approaches, and other outcomes were too sparsely reported to support these exploratory analyses. We did not include comparative effectiveness studies, which may have helped illuminate the importance of components.
However, other reviews and pooled analyses that have included comparative effectiveness studies, found no association between effect size and a number of specific components or therapist behaviors, with the possible exception of self-monitoring.229,230 An integrative data analysis of individual-level data from 31 brief motivational interventions found that the largest effects were seen for interventions with the highest degree of personalization and breadth of coverage (operationalized as the number of different components addressed). Interestingly, however, when the interventions were minimally personalized, effects were larger when fewer components were addressed than when many components were covered, suggesting a simpler message had more impact when the intervention was not personalized.231 Another study found that a stronger therapeutic alliance was associated with greater declines in drinking across multiple therapeutic approaches, which is likely more reflective of interventionist skill than specific change-promoting techniques.232 One review of interventions in adolescents and young adults found that motivational interviewing and the use of decisional balance and goal-setting exercises were associated with larger effects in trials of interventions to reduce alcohol use, but this review included both universal and indicated prevention interventions, a wider range of settings, and did not require recruitment through screening, so applicability is somewhat limited.217

Implementation of Interventions to Reduce Unhealthy Alcohol Use

Several large-scale implementation studies have demonstrated that it is feasible to implement screening programs in real-world primary care systems. These studies have found that implementation of screening or SBIRT programs for unhealthy alcohol use substantially increased the odds that patients were screened for unhealthy alcohol use and received appropriate counseling.233,234,235 Some studies have found that having support staff or embedded behavioral health practitioners conduct screening and interventions improves rates of these services over physician-based screening235-237 and that behavioral health practitioners provided fewer referrals to specialty care (instead providing the counseling themselves), likely because they had more time than pediatricians to address the patients’ alcohol and substance use.235 These findings are consistent with those of a recent review of implementation approaches, which concluded that implementation programs should ideally include a combination of patient-, clinician-, and organizational-oriented approaches and involve midlevel health professionals as well as physicians.238

A 12-week implementation study found that training and support plus financial reimbursement were associated with increases in screening for unhealthy alcohol use and brief interventions for those screening positive in 120 primary health care units across five European countries. Free access to a Web-based brief intervention tool without training and financial reimbursement did not increase screening or intervention delivery in this study.239 This study further found that continuous provision of training and support, sufficient time to learn the intervention techniques, and time to tailor training to individual experienced barriers were rated as important by clinicians.240

In terms of intervention contact, many interventions in the trials included in this review were
entirely consistent with published guidelines (Table 3), particularly those that were conducted in primary care settings and that involved direct contact with an interventionist. Several trials referred to an NIAAA guide or the Feedback, Responsibility, Advice, Menu, Empathy, Self-efficacy (FRAMES) framework, which was explicitly incorporated into the WHO guide. The guides have not specifically incorporated the use of personalized normative feedback; however, it certainly fits under the recommendation to provide feedback on the patient’s drinking level, universal to all of these guides.

**Applicability**

One strength of this evidence base is its relatively high applicability to United States primary care. Most of the included studies were conducted in primary care settings and/or in the United States. Although some studies examining test performance had high-risk samples with higher than average rates of unhealthy alcohol use, the percent of unhealthy alcohol users generally ranged from the low-20s to low-30s in adults, which is consistent with the proportion of adults with heavy use episodes in the past month in the United States. The rates of AUD in the test performance studies in adults most commonly ranged from 9 to 11 percent, which is slightly, but not substantially, higher than the 6.0 percent nation-wide rate of AUD. Among intervention trials, effect sizes in primary care-based studies and those conducted in the United States were generally comparable or larger than the full body of evidence, and most studies did not have highly restrictive inclusion criteria, suggesting the results of our pooled analyses are likely to hold up in primary care settings. In addition, a wide range of subpopulations were represented in the evidence, including, for example, studies targeting racial and ethnic minority patients, different age ranges, males and females, different geographic regions, pregnant and postpartum women, economically disadvantaged populations, veterans, and persons with medical comorbidities.

**Limitations of Our Review**

One potential limitation to our approach is that we did not include comparative effectiveness trials, which have the potential to identify important features or mechanisms of change. As discussed above, however, several other studies and reviews have not been able to identify key treatment components or mechanisms of change, even when examining comparative effectiveness studies.

We also did not include evidence regarding use of medication in treatment of AUD. While this is primarily relevant to treatment of more severe disorders rather than screen-detected samples, medication would likely be appropriate for some patients identified through screening.

Among adolescents, we did not include trials addressing prevention of unhealthy alcohol use. This was outside the scope of our review but may be an important body of literature to consider when developing recommendations for adolescents.

Also, our estimate of drinks per week has an extra level of uncertainty due to differences in the
size of a standard drink across studies. The most commonly reported definition of a standard drink was 10 grams of ethanol/drink, but ranged from 8 to 14. We used 14 grams as a conversion factor when studies reported grams rather than drinks, for comparability with studies conducted in the United States, which presumably used a conversion factor of 14. An ideal approach would have been to convert drinks per week to grams of ethanol/week; however, data were insufficient to do so. Since some countries do not have published standard drink sizes measured in grams/ethanol we could not apply conversion factors based only on country in which the study took place.

**Limitations of the Studies and Future Research Needs**

We found no trials comparing screening programs with usual care (without universal screening). While these trials are difficult, and some kind of baseline assessment would be needed to understand baseline comparability between groups, it would nevertheless be useful to conduct a study with an unscreened comparison group to understand the population-level impact of screening in primary care settings.

We found no eligible studies that evaluated the versions of the AUDIT and AUDIT-C recently developed for the United States (USAUDIT and USAUDIT-C). The USAUDIT/USAUDIT-C is an adaptation of the AUDIT/AUDIT-C to the United States, standard drink size that modifies the response categories for the quantity/frequency items to allow alignment with NIAAA recommendations. For example, the item asking about heavy use episodes was changed to be \(5/4\) or more drinks on one occasion for males/females, from six or more drinks in the original AUDIT/AUDIT-C. Indeed, one study has determined that the AUDIT-C miscategorizes up to 21 percent of individuals in the United States due to the mismatch between the response categories and NIAAA-specific recommendations.\(^{241}\) Although none of the included studies specifically assessed the USAUDIT relative to a reference standard, it is likely comparable to or better than the AUDIT and AUDIT-C, probably with fewer false positives in a U.S.-based population. For example, women drinking one drink per day score positive on the AUDIT-C but are still within NIAAA recommended levels; these women would not screen positive on the USAUDIT-C but would screen positive on the AUDIT-C. Indeed, in our review, studies assessing one- or two-item screeners that used \(5/4\) (males/females) drinks (as in the USAUDIT) tended to report better sensitivity than those using the six-drink standard (as in the original AUDIT), supporting its use in the United States population. Test performance studies of the USAUDIT and USAUDIT-C are needed to confirm its accuracy in identifying unhealthy alcohol users.

One important limitation of the evidence on the benefits and harms of alcohol interventions is the lack of a consistently reported group of outcomes. The most commonly reported outcome was drinks per week, which was reported in only about two-thirds of the trials in adults. Other important outcomes were reported much less frequently. It would be beneficial for trials to routinely report outcomes with the greatest clinical meaning, such as the proportion of participants with alcohol use within recommended limits, the proportion with heavy use episodes, and health (including alcohol-related medical conditions), social, and legal outcomes. This includes reporting of health care utilization reflecting emergent or serious health impacts (e.g., emergency department visits, inpatient stays), and patient-reported health outcomes such as
alcohol-related problems or consequences would also be valuable. The TrEAT trial provides an excellent example of using multiple objective sources such as electronic medical records, government crime and transportation databases as well as self-report.

It would also be useful for trials to plan \textit{a priori} to report subgroup effects in important subpopulations, such as by age group, sex, race/ethnicity, baseline severity. It is preferable to test interaction terms, although recognizing that these may be underpowered, reporting of subgroup effects could still be useful, even in the absence of statistically significant interactions.

We found only two trials of interventions to reduce alcohol use in adolescents, even though alcohol use in adolescents is relatively common. The one other trial we found (but excluded due to having only 3 months of followup) did not show positive results but was quite small (n=42), so results could have been limited more by power than by effect size.\cite{242} In addition, we found one systematic review, which was not included in our evidence base, of experimental and quasi-experimental studies of brief alcohol interventions in any setting. This review identified 24 studies in adolescents.\cite{217} It found an estimated reduction of 1.3 fewer drinking days per month and an 8-percentile improvement in alcohol-related problems with brief interventions, which is promising in this age group. Almost all of these were conducted in school settings, so how these findings translate to primary care settings is not yet understood. More studies are needed in adolescents outside of school settings, particularly in primary care settings.

Although we found many trials targeting young adults, most of those involved only very brief interventions and had relatively small effects. Given the very high rates of unhealthy alcohol use in young adults, further development of interventions that could have a larger and more long-lasting impact is warranted, such as interventions with more and/or longer contacts and that involve interacting with a person rather than purely computer-based. Additionally, testing some of the computer-based interventions that showed the largest absolute effects in a health care setting would be useful, as these interventions would certainly be feasible for a health system to offer, and could have wide reach.

Data were also limited in older adults, with only 4 intervention trials. Given that NESARC data show increasing rates of unhealthy alcohol use in older adults and given that the largest effects were seen in the oldest trial (published almost 20 years ago), ensuring that interventions continue to be effective in the current and future generations of older adults is important. In addition, the existing studies had limited racial/ethnic and socioeconomic diversity, so research including these important subpopulations is imperative.

Among general adult populations, areas for future research include more studies exploring features to facilitate dissemination and implementation would be useful. In addition, more studies exploring primary care-based treatment approaches in populations with comorbid medical and mental health conditions that are primary care-based would be useful.

One concern with this literature is the validity of self-report, given that it may be difficult to recall drinking amounts accurately and participants might find it uncomfortable to admit to high levels of alcohol use, particularly after participating in an intervention to reduce their use. Unfortunately, there is no good, widely available, objective measure of alcohol use, so studies
necessarily rely on self-report. Some studies have suggested that accurate alcohol use can be collected through self-report, if done carefully, as it was with many of the included studies. Included trials typically described emphasizing the confidential nature of the data collection, and in many cases used mailed questionnaires or computer-based data collection instruments to minimize demand characteristics. Twelve trials had participants identify collateral informants who could confirm their alcohol use, which is thought to improve self-report accuracy. In addition, retrospective measures with shorter recall periods (e.g., 1 week, 1 month) tend to have better accuracy that longer recall periods (e.g., 1 year), and most recall periods were 1 to 3 months in the included trials. Findings also suggest that retrospective recall leads to underestimates of drinking quantity, particularly when heavy drinking is involved, yet the included trials employed retrospective strategies. To compensate for this, many trials used the timeline followback approach or similar calendar-based methods to estimate daily drinking, which have better accuracy than general recall items. Most of these limitations would likely apply equally to intervention and control participants, thus limiting precision but not necessarily biasing results. We hypothesized that social desirability bias may be stronger in individuals who have participated in an alcohol-reduction intervention but could not find studies that explored this. Careful assessment—such as use of timeline followback methods—covering relatively short time periods, with blinded interviewers or neutral data collection methods such as computer-based or mailed questions and strenuous assurances of confidentiality, are important for future studies in this area.

Another important limitation to the body of evidence was the inability to tease out the contribution of several study characteristics to effect size heterogeneity because characteristics tended to cluster together. The field of alcohol research in nondependent users has moved toward lower-intensity interventions, which can be delivered to large numbers of people more easily. Thus, newer trials generally enrolled more participants, had less-restrictive inclusion criteria in terms of alcohol use severity, provided brief interventions, and frequently targeted college-aged adults. Continued exploration of effects in primary care settings among adults of all ages, with subgroup analyses among different age groups, would be valuable for understanding the impact of these interventions in current primary care settings.

It would also be useful to see trials that evaluate the effectiveness of brief or electronically based interventions delivered through other existing public health infrastructure, such as already-existing Web sites or smoking cessation quit lines. For example, one trial in college students delivered a personalized, normative feedback intervention through Facebook and found reductions in drinking 3 months later. More studies with longer followup utilizing such existing resources would explore the potential to leverage these mechanisms to deliver alcohol use interventions more broadly.

Ongoing studies are reported in Appendix J.

Conclusion

We found no direct evidence on the impact of screening programs for unhealthy alcohol use. Among adults, screening instruments are available that can accurately identify unhealthy alcohol
users that are feasible for use in primary care settings, and interventions in those who screen positive are associated with reductions in unhealthy alcohol use. Very limited evidence suggests a possible beneficial impact on hospitalizations and substance use violations, but the impact on all-cause mortality is uncertain, and other health outcomes showed no clear benefit. There is no evidence to suggest that these interventions have unintended harmful effects. More evidence is needed to determine whether screening for unhealthy alcohol use is beneficial for adolescents.

* Optimal cutoffs could vary by study and were selected as either the optimal cutoff determined by the authors or the reviewers.

Notes: McGinnis is an all male study. 4+ drinks includes modified AUDIT-3 (lower threshold for females and older adults) and SUBS. 6+ drinks includes AUDIT-3. Quant X Freq includes the first two items from the AUDIT; the score can range from 0 to 8.

### Table 1. Unhealthy Alcohol Use: Terms and Definitions

<table>
<thead>
<tr>
<th>Term</th>
<th>Source</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>Low-risk use / Low-risk use</td>
<td>ASAM</td>
<td>Consumption of alcohol below the amount identified as hazardous and used in situations not defined as hazardous.</td>
</tr>
<tr>
<td>Risky/At-risk use</td>
<td>NIAAA</td>
<td>Consumption of alcohol above recommended daily, weekly, or per occasion amounts, but not meeting criteria for alcohol use disorder. For women: no more than 3 drinks per day and no more than 7 drinks per week. For men: no more than 4 drinks per day and no more than 14 drinks per week. Should avoid alcohol completely. For adolescents, women who are pregnant or trying to get pregnant, adults when planning to drive a vehicle or operate machinery, taking medication that interacts with alcohol, they have a medical condition that alcohol can aggravate.</td>
</tr>
<tr>
<td>Unhealthy use</td>
<td>ASAM</td>
<td>Any use that increases the risk or likelihood for health consequences (hazardous use [see below]), or has already led to health consequences (harmful use [see below]).</td>
</tr>
<tr>
<td>Hazardous use</td>
<td>WHO</td>
<td>A pattern of substance use that increases the risk of harmful consequences for the user. In contrast to harmful use, hazardous use refers to patterns of use that are of public health significance despite the absence of a current alcohol use disorder in the individual user.</td>
</tr>
<tr>
<td>Harmful use</td>
<td>WHO</td>
<td>A pattern of drinking that is already causing damage to health. The damage may be either physical (e.g., liver damage from chronic drinking) or mental (e.g., depressive episodes secondary to drinking). This is the description for ICD-10 code F10.1, which is also labeled “Alcohol Abuse” in the 2018 ICD-10-CM codebook.</td>
</tr>
<tr>
<td>Alcohol use disorder</td>
<td>DSM-5</td>
<td>A maladaptive pattern of alcohol use leading to clinically significant impairment or distress, as manifested by two (or more) of the following, occurring within a 12-month period: 1. Having times when the patient drank more, or longer, than intended. 2. More than once wanted to cut down or stop, tried it, but could not. 3. Spending a lot of time drinking or being sick/getting over the aftereffects of drinking. 4. Wanting to drink so badly that they could not think of anything else. 5. Found that drinking (or being sick from drinking) often interfered with taking care of home or family responsibilities, caused problems at work, or caused problems at school. 6. Continuing to drink even though it was causing trouble with family and friends. 7. Given up or cut back on activities that were important or interesting in order to drink. 8. More than once gotten into situations while or after drinking that increased the chances of getting hurt (e.g., driving, swimming, unsafe sexual behavior). 9. Continued to drink even though it was causing depression or anxiety, other health problems, or causing memory blackouts.</td>
</tr>
<tr>
<td>Term</td>
<td>Source</td>
<td>Definition</td>
</tr>
<tr>
<td>-------------------------------------------</td>
<td>---------------</td>
<td>------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td></td>
<td>10. Having to drink much more than previously in order to get the desired effect, or finding that the usual number of drinks had much less effect than previously.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>11. Experiencing the symptoms of withdrawal after the effects of alcohol were wearing off, such as trouble sleeping, shakiness, restlessness, nausea, sweating, racing heart, or seizure.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Severity is determined based on the number of symptoms present:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Mild: 2-3 symptoms</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Moderate: 4-5 symptoms</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Severe: 6 or more symptoms</td>
</tr>
<tr>
<td>Binge drinking / heavy drinking episodes*</td>
<td>NIAAA</td>
<td>A pattern of drinking that brings blood alcohol concentration levels to 0.08 g/dL. This typically occurs after 4 drinks for women and 5 drinks for men—in about 2 hours.</td>
</tr>
<tr>
<td></td>
<td>SAMHSA</td>
<td>Drinking 5 or more alcoholic drinks on the same occasion on at least 1 day in the past 30 days.</td>
</tr>
<tr>
<td>Heavy drinking</td>
<td>SAMHSA</td>
<td>Drinking 5 or more drinks on the same occasion on each of 5 or more days in the past 30 days.</td>
</tr>
<tr>
<td>Alcohol dependence</td>
<td>WHO/ICD-10-CM</td>
<td>Three or more of the following at some time during the previous year:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1. A strong desire or sense of compulsion to take the substance;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2. Difficulties in controlling substance-taking behaviour in terms of its onset, termination, or levels of use;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>3. A physiological withdrawal state when substance use has ceased or been reduced, as evidenced by: the characteristic withdrawal syndrome for the substance; or use of the same (or a closely related) substance with the intention of relieving or avoiding withdrawal symptoms;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>4. Evidence of tolerance, such that increased doses of the psychoactive substance are required in order to achieve effects originally produced by lower doses (clear examples of this are found in alcohol- and opiate-dependent individuals who may take daily doses sufficient to incapacitate or kill nontolerant users);</td>
</tr>
<tr>
<td></td>
<td></td>
<td>5. Progressive neglect of alternative pleasures or interests because of psychoactive substance use, increased amount of time necessary to obtain or take the substance or to recover from its effects;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>6. Persisting with substance use despite clear evidence of overtly harmful consequences, such as harm to the liver through excessive drinking, depressive mood states consequent to periods of heavy substance use, or drug-related impairment of cognitive functioning; efforts should be made to determine that the user was actually, or could be expected to be, aware of the nature and extent of the harm.</td>
</tr>
</tbody>
</table>

*According to ASAM the preferred term is a heavy drinking episode.

| NIAAA 2005                  | Helping Patients Who Drink Too Much: A Clinician’s Guide     | Single-item screener: How many times in the past year have you had 4/5 [F/M] or more drinks in a day? (Plus pre-screen asking if they sometimes drink beer, wine, or other alcoholic beverages) | • Assess for use disorders  
  • Advise and Assist (separate pathways for patients with and without an alcohol use disorder): state conclusions and recommendations, gauge readiness to change, approach/discussion points provided based on readiness to change  
  • Follow up: Continued discussions and support at subsequent visits, emphasizes empathy, supporting positive change; revisit goals/plan, engage others, consider referrals, address coexisting conditions, coordinate care, et cetera | Clinician guide on medication for alcohol dependence, Patient education materials, Links/lists of other resources |
| NIAAA 2011                  | Alcohol Screening and Brief Intervention for Youth: A Practitioner’s Guide | 2 age-specific items about friends’ drinking and patients’ drinking frequency                  | • Guide patients (non-users): reinforce healthy choices, elicit/affirm reasons not to use alcohol, educate about effects of alcohol on health  
  • Assess risk level (users)  
  • Advise and assist (users): Collaborate on personal goal and action plan; advise against drinking and driving and riding with someone who has been drinking; plan a full psychosocial interview; further approach/discussion points provided based on risk level  
  • Follow up: Continued discussions and support at subsequent visits, emphasizes empathy, supporting positive change; revisit goals/plan, engage parents, consider referrals, et cetera | Links/lists of additional resources for clinicians, patients, parents |
| CDC 2014                    | Planning and Implementing Screening and Brief Intervention for Risky Alcohol Use | NIAAA single-item screener or USAUDIT-C (items 1-3 of the US version of the AUDIT)            | • Assess severity  
  • Provide feedback on alcohol use  
  • Listen for and reinforce change talk (e.g., explore pros and cons or alcohol use, assess readiness to change)  
  • Advise, if patient agrees to hear your advice  
  • Provide options: discussion of goals, consider action plan, consider referrals, seek agreement for follow up | Implementation plan, patient handouts, provider training materials, links/lists of additional resources |
| AAFP 2017                   | Addressing Alcohol Use Practice Manual: An Alcohol Screening and Brief Intervention Program | Not specified                                                                                   | • Advise every risky drinker to reduce alcohol use or quit.  
  • Assess whether the patient is willing to reduce use or quit  
  • Assist: If willing to change, develop personalized plan, consider referral; employ motivational interviewing techniques such as expressing empathy, supporting self-efficacy, pointing out previous successes, rolling with resistance, helping patients see the discrepancy between where they are and where they would like to be.  
  • Arrange follow up | Implementation plan, links/lists of additional resources |

* More than one value reported because the data was presented by subgroups (e.g., sex, race)
† NIAAA-recommended screening instrument for adults: “How many times in the past year have you had 5/4 (M/F) or more drinks in a day?” preceded by a pre-screening question that assessed alcohol use (“Do you sometimes drink beer, wine, or other alcoholic beverages?”). NIAAA-recommended screening instrument for adolescents: “Do you have any friends who drank beer, wine, or any drink containing alcohol in the past year?” and “In the past year, on how many days have you had more than a few sips of beer, wine, or any drink containing alcohol?” (For age 9-14 years, the first question asks about friends’ use; for age 14-18, the first question asks about person use)
§ McGinnis et al. was an outlier and was not included in the ranges presented. It reported the following: for AUDIT-C, ≥4 cutoff (male) sensitivity 0.63 and specificity 0.90 for unhealthy alcohol use.

**Abbreviations:** AUD = alcohol use disorder; AUDIT = Alcohol Use Disorders Index Test; AUDIT-C = Alcohol Use Disorders Index Test, Consumption; NA = not applicable; NIAAA = National Institute on Alcohol Abuse and Alcoholism; Se = sensitivity; Sp = specificity; US = United States

<tr>
<td>KQ2. Screening accuracy</td>
<td>k= 45, n=277,881</td>
<td>For adolescents, data supported the use of the NIAAA Youth Screen and other one- or two-item screeners to detect AUD, however data were insufficient to determine whether brief (1-3 item) screeners or the AUDIT can detect unhealthy use. Preliminary evidence suggests lower cutoffs than the standard ≥8 would be preferred for the AUDIT if used. For adults, brief (1-3 item) screeners commonly reported sensitivity and specificity between 0.70 and 0.85, typically having better sensitivity than the full AUDIT for identifying the full spectrum of unhealthy use. However, the AUDIT tended to have higher specificity, particularly at the standard cutoff of ≥8. Evidence supports the use of brief instruments as initial screeners, where high sensitivity and lower specificity would be desirable, followed by a longer instrument, such as the AUDIT, with greater specificity.</td>
<td>Reasonably consistent, reasonably precise (Adolescents, to detect AUD)</td>
<td>None suspected</td>
<td>Good: 17 Fair: 28</td>
<td>Information around the administration of the screening test and reference standard often not well reported (order of tests, blinding of interviewer to the results of the index test while administering the reference standard).</td>
<td>Moderate (Adolescents, to detect AUD) Insufficient (Adolescents, to detect full spectrum of unhealthy alcohol use) High (Adults)</td>
<td>Many in US primary care, including studies covering both general populations and targeted subgroup with comorbidities and in different types of settings (e.g., including the VA and Indian Health Service). U.S.-based studies outside of primary care included epidemiologic surveys with sampling representative of the U.S. population, with oversampling of race and ethnic minorities in some cases. Young adult studies primarily in college settings.</td>

</thead>
<tbody>
<tr>
<td><strong>KQ4a. Benefits of interventions: Alcohol use and other risky behavior</strong></td>
<td>k=68 RCTs n=36,528</td>
<td>Interventions reduced drinks/week (WMD=−1.59 [95% CI, −2.15 to −1.03]), the proportion exceeding recommended drinking limits (OR=0.60 [95% CI, 0.53 to 0.67]), and the proportion reporting a heavy use episode (OR=0.67 [95% CI, 0.58 to 0.77]), and increased the proportion of pregnant women reporting abstinence (OR=2.26 [95% CI, 1.43 to 3.56]). Outcomes were generally reported at 6 to 12-month follow-up, or during the late pregnancy or early postpartum period for abstinence during pregnancy. Benefits remained through 24 months or beyond in 4 of 7 trials with longer-term outcomes. Heterogeneity was high and effect size was associated with a number of study (but not intervention) characteristics. Reduction in self-reported drinking after driving in 2 of 3 trials.</td>
<td>Inconsistent and imprecise for adolescents Reasonably consistent, reasonably precise for adults</td>
<td>Suspected, due to detected small studies bias</td>
<td>Good: 10 Fair: 58</td>
<td>Inconsistency of outcomes reported and some important outcomes sparsely reported, such as proportion meeting or exceeding recommended drinking limits; risk of social desirability bias</td>
<td>Moderate</td>
<td>Majority of trials conducted in the U.S., in primary care, and in the past 10 years, with representation from a wide range of important subpopulations (e.g., young adults, older adults, pregnant and postpartum women, low income, with comorbidities, race/ethnic minorities)</td>
</tr>
<tr>
<td><strong>KQ4b. Benefits of interventions: Health, social, and legal outcomes</strong></td>
<td>k=41 n=20,324</td>
<td>No evidence in adolescents. In adults, studies reported a statistically nonsignificant reduction in all-cause mortality (OR=0.64 [95% CI, 0.34 to 1.19]), but underpowered, usually unclear ascertainment methods, and likely overestimates effect, since many studies were conducted in the U.S., in primary care, and in the past 10 years, with representation from a wide range of important subpopulations (e.g., young adults, older adults, pregnant and postpartum women, low income, with comorbidities, race/ethnic minorities)</td>
<td>Possible for mortality, since all studies reporting had at least one death.</td>
<td>Good: 6 Fair: 35</td>
<td>Wide range of outcomes reported with little replication and few studies reporting any particular outcome; mortality</td>
<td>Insufficient (Adolescents) Low (Adults)</td>
<td>Majority of trials conducted in the U.S., in primary care, and in the past 10 years, with representation from a wide range of important subpopulations (e.g., young adults, older adults, pregnant and postpartum women, low income, with comorbidities, race/ethnic minorities)</td>

Screening/Interventions for Unhealthy Alcohol Use 138 Kaiser Permanente Research Affiliates EPC
<table>
<thead>
<tr>
<th>DSM-IV</th>
<th>Symptoms (past year)</th>
<th>DSM-5</th>
</tr>
</thead>
<tbody>
<tr>
<td>Any 1= Alcohol Abuse</td>
<td>Found that drinking (or being sick from drinking) often interfered with taking care of home or family responsibilities, caused problems at work, or caused problems at school.</td>
<td>2+ symptoms = Alcohol Use Disorder</td>
</tr>
<tr>
<td></td>
<td>More than once gotten into situations while after drinking that increased the chances of getting hurt (e.g., driving, swimming, unsafe sexual behavior).</td>
<td>Mild: 2-3 symptoms</td>
</tr>
<tr>
<td></td>
<td>More than once gotten arrested, been held at a police station, or had other legal problems because of drinking (Not in DSM-5)</td>
<td>Moderate: 4-5 symptoms</td>
</tr>
<tr>
<td></td>
<td>Continued to drink even though it was causing trouble with family and friends.</td>
<td>Severe: 6+ symptoms</td>
</tr>
<tr>
<td>Any 3 = Alcohol Dependence</td>
<td>Had to drink much more than previously in order to get the desired effect, or finding that the usual number of drinks had much less effect than previously.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Experienced the symptoms of withdrawal after the effects of alcohol were wearing off, such as trouble sleeping, shakiness, restlessness, nausea, sweating, racing heart, or seizure.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Had times when the patient drank more, or longer, than intended.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>More than once wanted to cut down or stop, tried it, but could not.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Spent a lot of time drinking or being sick/getting over the aftereffects of drinking.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Given up or cut back on activities that were important or interesting in order to drink.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Continued to drink even though it was causing depression or anxiety, other health problems, or causing memory blackouts.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Wanted to drink so badly that the patient could not think of anything else. (Not in DSM-IV)</td>
<td></td>
</tr>

</thead>
<tbody>
<tr>
<td><strong>Aim</strong></td>
<td>Screening for unhealthy alcohol use and interventions for nondependent unhealthy alcohol use, with or without addressing other substances or behaviors</td>
<td>Studies in which the only aim is targeting another behavior (e.g., drug or tobacco use) (i.e., change in alcohol use is not a stated aim, even if it is a reported outcome)</td>
</tr>
<tr>
<td><strong>Condition</strong></td>
<td>Unhealthy alcohol use*, including:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Risky or hazardous use: consumption of alcohol above recommended daily, weekly, or per-occasion amounts; consumption levels that increase the risk for health consequences</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Harmful use: a pattern of drinking that is already causing damage to health; damage may be either physical (e.g., liver damage from chronic drinking) or mental (e.g., depressive episodes secondary to drinking)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• A diagnosis of an alcohol use disorder (e.g., according to Diagnostic and Statistical Manual of Mental Disorders [DSM] or International Classification of Diseases [ICD] diagnostic systems)</td>
<td></td>
</tr>
<tr>
<td><strong>Population</strong></td>
<td>All KQs: Adolescents and adults (age ≥12 years)</td>
<td>Studies limited to:</td>
</tr>
<tr>
<td></td>
<td>KQs 1–3: Studies whose participants are not selected on the basis of alcohol use or a related behavior or condition</td>
<td>• Treatment-seeking individuals (including those responding to recruitment advertising)</td>
</tr>
<tr>
<td></td>
<td>KQs 4, 5: Studies in which at least 50% of the enrolled sample is recruited via population-based screening</td>
<td>• Persons with concomitant psychotic disorders (e.g., schizophrenia)</td>
</tr>
<tr>
<td></td>
<td>A priori subpopulations at greater risk for unhealthy alcohol use or its consequences will be examined based on the following: age, sex, race/ethnicity, socioeconomic status, pregnancy status, concurrent unhealthy drug use, severity of disorder, and presence of comorbid mental health conditions</td>
<td>• Persons presenting in an emergency setting for alcohol-related issues (e.g., motor vehicle injury)</td>
</tr>
<tr>
<td></td>
<td>• Other groups not generalizable to primary care (e.g., psychiatric inpatients, persons who are court-mandated to treatment, incarcerated persons)</td>
<td>• KQs 4, 5: Persons with dependent alcohol abuse (or studies in which &gt;50% of the enrolled sample is persons with dependent alcohol use)</td>
</tr>
<tr>
<td><strong>Screening</strong></td>
<td>KQs 1, 3: Screening for alcohol use using a brief standardized instrument or set of questions that is conducted in person or via telephone, mail, or electronically</td>
<td>Studies without any screening instruments or question(s)</td>
</tr>
<tr>
<td></td>
<td>KQ 2: Accuracy of screening instruments will be limited to the following instruments, which are most widely used and feasible for application in primary care:</td>
<td>• Laboratory tests</td>
</tr>
<tr>
<td></td>
<td>• National Institute on Alcohol Abuse and Alcoholism (NIAAA) single- (for adults) or two-item (for adolescents) screening test, or comparable, including the Brief Screener for Tobacco, Alcohol, and other Drugs (BSTAD) (for adolescents)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Alcohol Use Disorders Identification Test (AUDIT), its abbreviated version (AUDIT-C), and variants of these</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Alcohol, Smoking, and Substance Involvement Screening Test (ASSIST) (for accuracy of detecting alcohol use only)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• Comorbidity Alcohol Risk Evaluation Tool (CARET) (for the elderly)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• TWEAK and T-ACE (for pregnant women)</td>
<td></td>
</tr>

*Good quality studies generally meet all quality criteria. Fair quality studies do not meet all the criteria but do not have critical limitations that could invalidate study findings. Poor quality studies have a single fatal flaw or multiple important limitations that could invalidate study findings. Critical appraisal of studies using *a priori* quality criteria are conducted independently by at least two reviewers. Disagreements in final quality assessment are resolved by consensus, and, if needed, consultation with a third independent reviewer.*

Evidence supporting current recommended limits

The National Institute on Alcohol Abuse and Alcoholism (NIAAA) recommends that men ages 21 to 64 years consume no more than four drinks per day and no more than 14 drinks per week (56 grams/day or 196 grams/week). Corresponding values for nonpregnant women and men aged 65 years and older are no more than three drinks per day and no more than 14 drinks per week (56 grams/day or 196 grams/week). The evidence regarding the association between average daily volume (ADV) of alcohol intake and mortality and morbidity generally supports these limits. A 2006 meta-analysis including 34 prospective cohort studies of all-cause mortality found that mortality risk begins to exceed the level of nondrinkers at an ADV of approximately 38 grams of ethanol (2.7 standard drinks, according to the U.S. standard of 14g per drink). Sex-specific dose response curves in the same meta-analysis found that the risk of all-cause mortality began to increase at a lower ADV for women (~35 grams) than men (~45 grams). Similar risk levels have been reported in older meta-analyses, with risk of all-cause mortality becoming higher for drinkers compared with nondrinkers at ADV 30 to 50 grams for women and 40 to 70 grams for men. The evidence regarding the increased risk of cardiovascular disease has been mixed, with some studies indicating a protective effect at lower levels of consumption, however recent evidence cautions that this effect may be misrepresented. A meta-analysis of 28 studies found an increased risk of coronary heart disease compared with nondrinkers at a heavy volume of consumption (ADV 89 grams, or 6.4 drinks/day). In addition, researchers found an increased risk of hemorrhagic stroke (ADV 50 grams, 3.6 drinks/day), ischemic stroke (ADV 100 grams, 7.1 drinks/day), and type 2 diabetes (men: ADV 60 grams, 4.3 drinks/day; women: ADV 50 grams, 3.6 drinks/day) in drinkers compared with abstainers. The results for stroke are similar to those found in another meta-analysis of 35 observational studies, however the evidence around the risk of type 2 diabetes have been mixed.

Evidence has shown that there is a dose-response relationship between alcohol intake and the risk of liver disease and cancer, with similar levels of increased harm reported for both conditions. The risk of developing liver cirrhosis was found to be increased at an ADV of 25 grams (or 1.8 drinks/day), with the increased risk for all types of liver disease reported at lower levels of consumption in women (7–13 drinks per week) than men (14–27 drinks per week). Evidence supports a likely causal relationship between excessive alcohol consumption and cancers of the oral cavity, pharyngeal, laryngeal, esophageal, liver, colon, rectal, and female breast. The meta-analysis by Corrao and colleagues found that the risk of developing pharyngeal, oral, colon, rectal, esophageal, laryngeal, liver, and breast cancers was significantly increased in drinkers compared with abstainers at ADVs of 25 grams and higher. These results were similar to those reported in other recent meta-analyses. However, the association between light to moderate alcohol consumption and cancer is less clear, and may vary by sex and cancer site. A 2015 systematic review and meta-analysis of two large U.S. cohort studies (n=135,965) found a small, but significant association between light to moderate drinking (<15 g/day for women and <30 g/day for men) and overall alcohol-related cancer risk when compared with abstainers. The risk of alcohol-related cancer among men was weaker than that among women, largely due to the strong association between light (5-14.9 g/day) consumption and female breast cancer (RR=1.13 [95% CI, 1.06 to 1.20]). Similarly, a 2013 systematic review and meta-analysis of 222 case-control and cohort studies found that light drinking (≤12.5 g/day) increased the risk of esophageal squamous cell carcinoma (RR=1.30 [95% CI, 1.09 to 1.56]).
Appendix B. Epidemiology of the Health Effects of Alcohol Use

oral cavity and pharynx cancer (RR=1.17 [95% CI, 1.06 to 1.29]), and female breast cancer (RR=1.05 [95% CI, 1.02 to 1.08]). However, this review did not find evidence of increased risk for cancer of the colorectum, liver, or larynx.

NIAAA recommends that pregnant women avoid alcohol altogether. Excessive alcohol use during pregnancy has been associated with adverse pregnancy outcomes, such as preterm birth, low birth weight, and Fetal Alcohol Spectrum Disorders. According to the U.S. Centers for Disease Control and Prevention (CDC), there is no safe amount of alcohol use during pregnancy or while trying to get pregnant; however, there has been considerable debate regarding whether low to moderate drinking is associated with adverse birth outcomes. A 2011 systematic review of 36 case control and cohort studies investigated the dose-response relationship between alcohol consumption before and during pregnancy and risks of low birth weight, preterm birth, and small-size-for-gestational age (SGA), and found that, compared with abstainers, the risk of low birth weight and SGA had no effect up to 10 grams/day and preterm birth had no effect up to 18 grams/day of pure alcohol consumption. Other reviews examining the effects of low to moderate prenatal alcohol exposure have had similar findings, citing a lack of consistent effect of alcohol on adverse pregnancy outcomes. However, some evidence suggests that low to moderate alcohol use during pregnancy may have more subtle effects on cognitive and neurological development, and that the prevalence of adverse pregnancy outcomes may depend on other factors, including the mother’s socioeconomic status.

Due to its ability to impair vision, psychomotor skills/abilities, reaction-time, and risk-taking judgment, alcohol has been associated with both intentional and unintentional injuries. Alcohol is commonly used prior to suicide. The risk of injury and violence is increased with ADV of 25 grams (1.8 drinks/day, RR=1.12, 95% CI 1.06-1.18). According to CDC, 7,266 suicides (23%) and 243,516 years of potential life lost (YPLL) were attributable to alcohol annually in 2001–2005. Alcohol also plays a key role in motor vehicle accidents, and even very low levels of consumption may impair driving. In general, the relationship between alcohol use and risk of motor vehicle accidents has been shown to be exponential. For example, dose-response curves suggest that consumption of 10 gram of pure alcohol is associated with a 24% increase in the odds of a motor vehicle accident (OR=1.24, 95% CI 1.18 to 1.31), while consumption of 120 grams is associated with an 52-fold increase (OR=52.0, 95% CI, 34.50 to 78.28). The legal limit of blood alcohol concentration (BAC) for operating a motor vehicle in all but one state in the United States is 0.08 g per 100 ml blood; however, there is evidence that BAC as low as 0.03 g/ml can impair faculties necessary for safe driving, such as vision, psychomotor skills/abilities, and reaction time. A BAC as low as 0.02 g/ml is associated with a 74% increase in the odds of a fatal motor vehicle injury (OR=1.74, 95% CI, 1.43 to 2.14); at a BAC of 0.08 g/ml the odds are much higher (OR=13.0, 95% CI, 11.1 to 15.2). Further, positive BACs in drivers younger than 21 as associated with higher relative crash risks.

Evidence for the benefits of reducing alcohol use

While the relationship between excessive alcohol use and mortality is well established in the epidemiological literature, the effect of reducing alcohol consumption and whether “safe” levels of alcohol use exist are still matters of public health debate. Several reviews have investigated the association between reductions in volume of alcohol use and all-cause mortality.
Appendix B. Epidemiology of the Health Effects of Alcohol Use

A 2013 systematic review of 16 studies among individuals with alcohol use disorders at baseline found that mortality risk decreased by more than half in individuals who reduced their drinking to abstention compared with those who continued heavy drinking (OR=0.35 [95% CI, 0.20 to 0.60]). Further, participants who reduced their drinking to below the study’s definition of heavy consumption (which varied across studies), but did not attain abstinence, also reduced their risk of mortality compared with those who continued heavy drinking (OR=0.61; 95% CI, 0.39 to 0.94). Another systematic review of 87 studies found that higher- (≥65 grams/day, or 4.6 U.S. drinks/day) and medium-volume (25–<45 g/day, 1.8 to 3.2 drinks/day) drinkers had a significantly higher risk of mortality compared with occasional drinkers (RR=1.52 [95% CI, 1.40 to 1.66] and RR=1.13 [95% CI, 1.05 to 1.22] respectively).

Studies have shown that higher levels of alcohol consumption are associated with increased blood pressure and the incidence of hypertension. However, there is evidence that the detrimental effects of alcohol on hypertensive heart disease can be mitigated by reducing alcohol consumption, especially among heavy drinkers. A 2017 systematic review and meta-analysis of 36 randomized controlled trials found that heavy drinkers (those drinking ≥6 drinks/day, where one drink=12 g) who reduced their drinking by 50 percent had significant improvements in systolic (MD= -5.50 mm Hg [95% CI, -6.70 to -4.30]) and diastolic blood pressure (MD= -3.97 [95% CI, -4.70 to -3.25]). However, this association did not hold true for moderate drinkers (2–3 drinks/day). Similarly, a 2001 systematic review and meta-analysis of 15 randomized controlled trials found that individuals who consumed ≥3 drinks/day at baseline and had significantly reduced their drinking by any amount experienced a significant reduction in systolic (MD= -3.31 mm Hg [95% CI, -2.52 to -4.10]) and diastolic blood pressure (MD= -2.04 mm Hg [95% CI, -1.49 to -2.58]).

Evidence related to a protective effect of alcohol use on cardiovascular disease and cognitive impairment

Some studies have characterized the relationship between alcohol consumption and various chronic conditions as a J-shaped curve, with slightly greater risk among abstainers compared with low to moderate drinkers, and progressive disease as drinking increases. This association has been most strongly supported by studies examining the association between low to moderate alcohol consumption and ischemic heart disease (IHD). A meta-analysis examining the impact of low to moderate alcohol consumption (<30 grams/day) on IHD risk found that moderate drinkers without heavy drinking episodes had a significantly lower risk for IHD than lifetime abstainers (RR=0.64 [95% CI, 0.53 to 0.71]), whereas moderate drinkers who engaged in heavy drinking episodes had a slight, but statistically nonsignificant, higher risk for IHD (RR=1.12 [95% CI, 0.91 to 1.37]).

Similarly, some studies have reported a protective effect in the association between low levels of alcohol consumption and varying degrees of cognitive impairment. A 2008 systematic review of 23 studies found evidence to suggest that small amounts of alcohol may protect against dementia (RR=0.63 [95% CI, 0.53 to 0.75]), but not for vascular dementia or general cognitive decline for older adults, aged ≥65 years, when compared with nondrinkers. The analysis identified a wide range within its included studies in which low to moderate alcohol consumption was found to be beneficial for reducing risk of dementia, from ≥1 drink/day to 1—28 units/week.
Appendix B. Epidemiology of the Health Effects of Alcohol Use

A meta-analysis of 15 studies found significant beneficial effects for light to moderate drinkers (range 1-28 drinks/week, varying by study) and dementia (RR=0.74 [95% CI, 0.61 to 0.91]), but also for vascular dementia (RR=0.75 [95% CI, 0.57 to 0.98]) and Alzheimer disease (RR=0.72 [95% CI, 0.61 to 0.86]) among older drinkers when compared with nondrinkers. On the other hand, this review did not find a beneficial effect of low to moderate alcohol consumption on cognitive decline.

However, this so-called “protective effect” remains controversial due to the potential misclassification of former heavy drinkers as abstainers in those studies, biasing the results in favor of light to moderate drinkers. For example, a meta-analysis examining the protective effect of moderate alcohol use on all-cause mortality found that estimates of mortality risk from alcohol were significantly altered by study design and characteristics, such as the misclassification of former drinkers as abstainers and lack of adjustment for confounding lifestyle variables. Moreover, a recent review summarized reasons for skepticism about the effects of low-dose alcohol consumption, including the lack of controlled studies investigating the association, the biological mechanisms for the health benefits being recently disconfirmed, evidence for adverse physiological effects of low-dose alcohol consumption, publication bias, and various confounding study population characteristics (e.g., benefits observed predominantly in Caucasian populations, moderate drinkers generally have healthier lifestyles, systematic exclusion of unhealthy drinkers).

† The original MAST included 25 questions and used a more complex scoring method; the version presented here represents the revised version used in practice today.
‡ This question is used in the Brief Screener for Tobacco, Alcohol, and other Drugs (BSTAD) to screen for alcohol use.
## Appendix D. Recommendations of Others

<table>
<thead>
<tr>
<th>Organization</th>
<th>Year</th>
<th>Recommendation</th>
</tr>
</thead>
</table>
| American Academy of Pediatrics (AAP) | 2016       | - Pediatricians should increase their capacity in substance use detection, assessment, and intervention.  
- Pediatricians should become familiar with adolescent SBIRT practices and their potential to be incorporated into universal screening and comprehensive care of adolescents in the medical home. |
|             | 2011 (Reaffirmed 2014) | - Providers should regularly screen all adolescent patients for alcohol use with validated screening tools and respond to screening results with the appropriate brief intervention. |
|             | 2001       | - Pediatricians should strongly advise against the use of alcohol and should assess their patients’ current use of alcohol using a nonjudgmental approach.  
- Pediatricians should discuss the hazards of alcohol and other drug use with their patients as a routine part of risk behavior assessment.  
- Pediatricians should be able recognize early signs and symptoms of alcohol abuse so they can properly evaluate, manage, and refer patients for further assessment and treatment as indicated. |
| U.S. Department of Veterans Affairs (VA) | 2015       | - For patients in general medical and mental health care settings, screening for unhealthy alcohol annually using the three-item Alcohol Use Disorders Identification Test-Consumption (AUDIT-C) or Single Item Alcohol Screening Questionnaire (SASQ) is recommended.  
- For patients without documented alcohol use disorder who screen positive for unhealthy alcohol use, physicians should provide a single, initial brief intervention regarding alcohol-related risks and advice to abstain or drink within nationally established age and gender-specific limits for daily and weekly consumption.  
- For patients with a diagnosis of a substance use disorder, physicians should offer referral for specialty substance use disorder care based on willingness to engage in specialty treatment. |
| Surgeon General of the United States | 2014       | - Clinicians should identify alcohol abuse disorders early and provide brief intervention, referral and treatment.  
- Clinicians should identify and screen patients for excessive drinking using a Screening, Brief Intervention, and Referral to Treatment (SBIRT) approach, implement provider reminder systems for SBIRT (e.g., electronic medical record clinical reminders) and evaluate the effectiveness of alternative methods for providing SBIRT (e.g., by phone or via the internet). |
| World Health Organization (WHO) | 2014       | - Health care providers should ask all pregnant women about their use of alcohol and other substances (past and present) as early as possible in the pregnancy and at every antenatal visit.  
- Health care providers should offer a brief intervention (structured therapy of short duration [5-30 minutes]) to all pregnant women using alcohol or drugs.  
- Health care providers managing pregnant or postpartum women with alcohol or other substance use disorders should offer comprehensive assessment and individualized care  
- Health care providers should, at the earliest opportunity, advise pregnant women dependent on alcohol or drugs to cease their alcohol or drug use and offer, or refer to, detoxification services under medical supervision where necessary and applicable. |
| American Congress of Obstetricians and Gynecologists (ACOG) | 2011 (Reaffirmed 2014) | - All women should be screened for alcohol use both before pregnancy and in their first trimester of pregnancy, using validated tools such as TACE  
- If unhealthy alcohol use is identified, brief counseling should be provided with referral to treatment if deemed necessary. |
## Appendix D. Recommendations of Others

<table>
<thead>
<tr>
<th>Organization</th>
<th>Year</th>
<th>Recommendation</th>
</tr>
</thead>
</table>
| National Institute for Health and Clinical Excellence    | 2011 | • Health and social care staff should receive alcohol awareness training that promotes respectful, non-judgmental care of people who misuse alcohol.  
• Health and social care staff opportunistically carry out screening and brief interventions for hazardous and harmful drinking as an integral part of practice.  
• Adults who misuse alcohol are offered evidence-based psychological interventions, and those with alcohol dependence that is moderate or severe can in addition access relapse prevention medication in accordance with NICE guidance.  
• Children and young people accessing specialist services for alcohol use are offered individual cognitive behavioural therapy, or if they have significant comorbidities or limited social support, a multicomponent program of care including family or systems therapy. |
| National Institute on Alcohol Abuse and Alcoholism (NIAAA) | 2007 | • Physicians should screen adult patients for at-risk drinking and provide brief counselling for at-risk drinkers.  
• Pharmacotherapy with medical management is recommended for treatment of alcohol dependence.  
• Patients with alcohol dependence should be referred for specialized alcohol counselling.  
• Patients with chronic alcohol dependence and serious medical complications should receive ongoing care management. |
| American Society of Addiction Medicine (ASAM)            | 1997 | • Primary care providers should routinely screen patients about alcohol use problems, screen for risk factors for development of alcohol dependence, and provide appropriate interventions and services. |

**Abbreviations:** AAP = American Academy of Pediatrics; ACOG = American College of Obstetricians and Gynecologists; ASAM = American Society of Addiction Medicine; NIAAA = National Institute on Alcohol Abuse and Alcoholism; NICE = National Institute for Health and Clinical Excellence; SBIRT = Brief Intervention and Referral to Treatment; TACE = Tolerance, Annoy, Cut down, Eye-opener; VA = U.S. Department of Veterans Affairs; WHO = World Health Organization

Appendix G. Test Accuracy for Alcohol Dependence

Adolescents

Alcohol Dependence

Single-item. Two studies assessed the accuracy of single-item screeners for alcohol dependence for a variety of age- and sex-specific cutoffs (Table 3). Frequency of alcohol use was used in two studies, with sensitivity ranging from 0.81 to 1.00 and specificity ranging from 0.71 to 0.97. A frequency of heavy episodic drinking screener (number of days they had 5 or more drinks per occasion in the past year) was used in one study to screen for dependence for a variety of age and sex groups, reporting sensitivity ranging from 0.42 to 0.83 and specificity ranging from 0.75 to 0.99. The lower sensitivity corresponded with younger age groups (males age 12—13 years, females age 12—15 years). One study used typical quantity of alcohol (drinks per drinking day) to screen for dependence among various age and sex groups, reporting sensitivity ranging from 0.68 to 1.00 and specificity ranging from 0.68 to 0.94. Sensitivity was higher for the younger age groups (sensitivity of 1.0 for males and females age 12—14 years).

AUDIT-C. No studies focused on adolescents used the AUDIT-C to screen for alcohol dependence.

AUDIT. One study reported accuracy at a cutoff of ≥8, finding a sensitivity of 0.75 (95% CI, 0.46 to 1.0) and specificity of 0.94 (95% CI, 0.92 to 0.96) (Table 3). Optimal cutoffs were lower (≥3 and ≥7) for two studies (sensitivity 1.00 [95% CI, 0.73 to 1.00] and 0.64 [95% CI, 0.32 to 0.88]; specificity 0.73 [95% CI, 0.70 to 0.77] and 0.75 [95% CI, 0.56 to 0.88], respectively). One study conducted with a U.S. primary care sample also reported the accuracy of the AUDIT at a cutoff of ≥5, with sensitivity of 0.83 (95% CI, 0.57 to 1.0) and specificity of 0.85 (95% CI, 0.82 to 0.88) (Table 3).

ASSIST. No studies focused on adolescents used the ASSIST to screen for alcohol dependence.

Young Adults

Alcohol Dependence

Single-item. No studies focused on young adults used a single-item test to screen for alcohol dependence.

AUDIT-C. One study assessed the accuracy of the AUDIT-C to screen for alcohol dependence (Table 7). Black and white females had high sensitivity (1.0 and 0.99, respectively, 95% CI, NR for this study) but low specificity (0.57 and 0.23, respectively) at a cutoff of ≥3. Similarly, at a cutoff of ≥4, black and white males had high sensitivity (0.84 and 0.97) and low specificity (0.51 and 0.25). The optimal cutoffs for four sex and race subgroups ranged from ≥4 to ≥8 (sensitivity 0.81 to 1.00; specificity 0.62 to 0.76).

AUDIT. Two studies reported the accuracy of the AUDIT to screen for DSM-IV dependence (Table 7). Only one reported the accuracy for a cutoff of ≥8, with a sensitivity of 0.93 (95% CI, 0.88, 0.96) and specificity of 0.60 (95% CI, 0.57, 0.62). This study examined
Appendix G. Test Accuracy for Alcohol Dependence

sex and race differences, so the optimal cutoff ranged from ≥7 to ≥13 for various race/sex groups. At the optimal cutoffs in two studies, sensitivity ranged from 0.75 to 0.86 and specificity ranged from 0.77 to 0.92.

ASSIST. No studies focused on young adults used the ASSIST to screen for alcohol dependence.

General Adults

Alcohol Dependence

Single-item. Four studies\(^88, 98, 117, 125\) assessed the accuracy of single-item screening tests to identify alcohol dependence (Table 11). Three studies used a 5/4+ drinks screening test with sensitivity ranging from 0.88 to 0.92 and specificity ranging from 0.82 to 0.84 at the optimal cutoffs, excluding subgroup analyses. One study\(^117\) among HIV patients and matched controls in the VA used a 6+ drinks screening test with sensitivity of 0.50 (95% CI, 0.38 to 0.62) and specificity of 0.91 (95% CI, 0.89 to 0.93) at the optimal cutoff; sensitivity was low in both the HIV+ patients (0.46 [95% CI, 0.32 to 0.63]) and the controls (0.52 [95% CI, 0.36 to 0.70]) in this study.

AUDIT-C. Six studies\(^98, 99, 117, 121, 124, 125\) examined the accuracy of the AUDIT-C to screen for alcohol dependence (Table 11). At a cutoff of ≥3 in five studies,\(^98, 99, 117, 121, 125\) sensitivity ranged from 0.74 to 1.00 and specificity ranged from 0.40 to 0.73. Three of the four studies reported sensitivity of 0.95 or higher; the fourth was the study that recruited HIV patients and matched controls from the VA (sensitivity 0.74 [95% CI, 0.62, 0.83]).\(^117\) At a cutoff of ≥4 in three studies,\(^98, 99, 121\) sensitivity ranged from 0.88 to 0.96 and specificity ranged from 0.62 to 0.80 outside of VA settings, but again sensitivity was lower in VA patients; the study with VA HIV patients and matched controls had sensitivity of 0.69 (95% CI, 0.57, 0.79) and corresponding specificity of 0.82 (95% CI, 0.79 to 0.84).\(^117\) The optimal cutoffs ranged from ≥3 to ≥5. At the optimal cutoffs for five studies,\(^98, 99, 121, 124, 125\) sensitivity ranged from 0.80 to 0.96 and specificity ranged from 0.65 to 0.87. The study in VA HIV patients and matched controls had lower sensitivity at 0.74 (95% CI, 0.62 to 0.83) and specificity of 0.73 (95% CI, to 0.70 to 0.76) at their optimal cutoff of ≥3.\(^117\)

AUDIT. Five studies reported the accuracy of the AUDIT at a cutoff of ≥8 (Table L). Three of these studies reported sensitivity ranging from 0.74 to 0.80 and specificity ranging from 0.85 to 0.94. Two studies, one reporting accuracy for a female subgroup only\(^124\) and another recruiting HIV patients and matched controls from the VA,\(^117\) reported lower sensitivity at 0.39 (95% CI, 0.25 to 0.56) to 0.56 (95% CI, 0.44 to 0.68), respectively, and corresponding specificity of 0.96 (95% CI, 0.94 to 0.98) and 0.92 (95% CI, 0.89 to 0.93). There was a wide range in optimal cutoffs (≥4 to ≥13). At the optimal cutoffs, sensitivity ranged from 0.67 to 0.96 and specificity ranged from 0.70 to 0.98.

ASSIST. No studies focused on general adults used the ASSIST to screen for alcohol dependence.
Appendix G. Test Accuracy for Alcohol Dependence

Older Adults

Alcohol Dependence

*Single-item.* No studies focused on older adults used a single-item screening test to screen for alcohol dependence.

*AUDIT-C.* One study reported accuracy among adults age 65 years or older who had drunk alcohol in the past year. At the optimal cutoff of ≥4, sensitivity was 0.88 (95% CI, 0.67 to 0.95) and specificity was 0.73 (95% CI, 0.71 to 0.74) (**Table 15**).

*ASSIST.* No studies focused on older adults used the ASSIST to screen for unhealthy alcohol use. No studies focused on older adults used the ASSIST to screen for alcohol dependence.

*CARET.* No studies focused on older adults used the CARET to screen for alcohol dependence.

Pregnant Women

Alcohol Dependence

*Single-item.* No studies focused on pregnant women used a single-item screening test to screen for alcohol dependence.

*AUDIT-C.* The study in a community sample of past-year alcohol users reported the accuracy of the AUDIT-C to screen for dependence in pregnant women who drank alcohol in the past year. At a cutoff of ≥3, sensitivity was 1.0 (95% CI, 0.70 to 1.00) and specificity was 0.70 (95% CI, 0.64 to 0.76). At the optimal cutoff of ≥4, sensitivity was 0.98 (95% CI, 0.70 to 1.00) and specificity was 0.86 (95% CI, 0.81 to 0.90) (**Table 18**).

*Other tools.* No studies focused on pregnant women used the AUDIT, ASSIST, TWEAK, or T-ACE to screen for alcohol dependence.

<td>Aalto, 2000163 Lahti Project</td>
<td>Adults</td>
<td>IG1</td>
<td>Participants received three brief 10-20-min interventions delivered by their general practitioner at baseline, 12, and 24 months. Participants were provided with a self-help booklet at baseline as a supplement to the brief interventions. The brief interventions consisted of the FRAMES (Feedback, Responsibility, Advice, Menu, Empathy, Self-efficacy) ingredients according to the needs of each individual participant, including information about the adverse effects of how the patient's alcohol consumption compared with recommended limits, feedback from the laboratory tests, information on the benefits of drinking less, and encouragement to reduce drinking. Laboratory tests were taken before each session and at each session the participant's alcohol consumption was inquired about in a structured way.</td>
<td>Individual face-to-face sessions</td>
<td>General counseling, PNF, FRAMES</td>
<td>Participants were advised to reduce drinking and contact their GP in the event of any health problems. In the case of abnormal laboratory values, appropriate clinical follow up was done.</td>
</tr>
<tr>
<td>Bertholet, 2015142</td>
<td>Young adults</td>
<td>IG1</td>
<td>Upon completing the baseline assessment, participants received personalized feedback including normative feedback indicating the percentage of people of the same age drinking more or less than participants (for weekly drinking and binge drinking frequency), feedback on the consequences of alcohol use ('me, my body and my mind'; 'me and the others'; 'me and my professional activities'; and 'me, violence and accidents') with a gradation of impact for each category between low and high according to the number of reported consequences), calorific value of reported consumption, computed blood alcohol consumption, computed blood alcohol concentration for reported consumption, indication of risk, information on alcohol and health, and recommendations indicating low-risk drinking limits. Participants also received an email thanking them for finishing the questionnaire along with a copy of the feedback.</td>

<td>Adults</td>
<td>IG2</td>
<td></td>
<td>Following screening, participants received a stage-tailored manual after the diagnostic procedure and computerized feedback based on core constructs of the Transtheoretical Model of behavior change. Participants received a maximum of three brief (30-40 min) counseling sessions based on motivational interviewing and behavioral change counseling. If participants reported reduction in alcohol consumption below study criteria for at-risk drinking and binge drinking within the last 4 weeks and also indicated a high self-efficacy to maintain the acquired behavioral change, defined as self-reported self-efficacy of at least 6 points on a 10-point Likert-Scale, they received no further intervention. If the first intervention was not successful, participants were offered a counseling session. The same procedure was conducted at the third contact after three months and the fourth contact after six months.</td>

**Young adults IG3**

The TLFB was administered by a trained RA. Participants were oriented to calendars for the previous 90 days, on which holidays and campus events were marked to prompt recall. The RA provided definitions of standard drinks and helped the participant reconstruct daily drinking, starting with the current week and working backwards. The TLFB included sequential assessment of alcohol use, drug use, and sexual behavior. After daily alcohol use was documented, the process was repeated for drug use and then for sexual behavior, on the same calendar. Participants received an appointment within the following week for the Enhanced BMI intervention. Interventionists utilized motivational interviewing techniques to administer the intervention. Basic BMI was enhanced with a decisional balance exercise, which occurred after the discussion of consequences and risk behaviors. The exercise used a worksheet with a 2x2 grid described as “a way to organize your thoughts about your current drinking and any potential changes you might want to make.” The top half of the grid was labeled with “Cutting down on my drinking: What I might lose/What I might gain”. The interventionist elicited information for each of the 4 boxes, summarized information, ending on the potential advantages of reducing alcohol use, and solicited the student's reactions. Students received the completed grid to take home.

<td>Daeppen, 2011&lt;sup&gt;145&lt;/sup&gt;</td>
<td>Young adults</td>
<td>IG1</td>
<td>The approximately 15-minute intervention intended to reinforce motivation to change behaviors related to alcohol use. The first aim was to introduce a behavior change perspective and discuss it in a non-judgmental, empathic and collaborative manner. The hypothesis was that an open discussion with additional reinforcement by a trained counselor around alcohol use and its repercussions on different life areas could heighten the conscript's awareness of the importance to change this behavior now or in the future. The model was not a structured intervention with a succession of phases, but rather a menu of strategies in the form of topics, or areas of conversation that the counselor might address, according to individual drinking status and readiness to change. Strategies consisted of: an opening strategy exploring lifestyle, general alcohol use, alcohol use within a typical day/session, then focusing on the hypothesis of a reduction in alcohol use among bingers or on the status quo among non-bingers; focusing on the pros and cons of alcohol use; evoking hypothetical changes in drinking patterns; exploring importance, ability, and confidence to change; eliciting commitment to change, and the identification of a hypothetical change. In order to avoid any confrontational dimension, the intervention did not include a personalized feedback.</td>

**Fleming, 1997**

**Project TrEAT (Trial for Early Alcohol Treatment)**

**Adults**

**IG1**

Participants were provided with a health booklet on general health issues and scheduled to see their personal physician for a brief intervention. Participants received two 15 min intervention sessions with their physician scheduled one month apart (brief intervention and reinforcement session). At the first session, participants were provided with a workbook that contained feedback regarding current health behaviors, a review of the prevalence of problem drinking, a list of the adverse effects of alcohol, a worksheet on drinking cues, a drinking agreement in the form of a prescription, and drinking diary cards. The intervention was based on protocols developed for the Medical Research Council (MRC). Participants received 2 follow up telephone calls from the clinic nurse 2 weeks after each physician-delivered intervention session.

**Therapeutic approach**

Individual face-to-face sessions,

**CM**

Participants were provided with a health booklet on general health issues and were instructed to address any health concerns in their usual manner.

**Fleming, 1999**

**Project GOAL (Guiding Older Adult Lifestyles)**

**Older adults**

**IG1**

The brief intervention was developed according to protocols used by the Medical Research Council trial and Project TrEAT and comprised a workbook containing feedback on the patient's health behaviors, review of problem-drinking prevalence, reasons for drinking, adverse effects of alcohol, drinking cues, a drinking agreement in the form of a prescription, and drinking diary cards. The intervention was delivered in two 10-15 min physician-delivered counseling sessions scheduled 1 month apart (a brief intervention and a reinforcement session). Participants received one follow up call from a clinic nurse 2 weeks after each visit.

**Therapeutic approach**

Individual face-to-face sessions,

**General counseling**

Participants received a general health booklet.

**Fleming, 2008**

**Postpartum women**

**IG1**

The intervention was based on protocols developed for Project TrEAT, and was modified for the Healthy Moms trial, after consultation with obstetricians, obstetrical nurses and

Experts in the field. The intervention protocol was contained in a workbook, which included scripted messages with feedback regarding current health behaviors, a review of the prevalence of problem drinking, a list of the adverse effects of alcohol focused on women and pregnancy, a worksheet on drinking cues, a drinking agreement in the form of a prescription, and drinking diary cards. The workbook was based on the principles of motivational interviewing and cognitive behavioral therapy. Participants received two 15-minute in-person sessions with the clinic nurse scheduled one month apart and two follow-up calls two weeks after each session. During the face-to-face sessions, the clinic nurse or obstetrician went through the workbook with the participant. The participants took the workbook home between visits and filled out a number of homework assignments focused on high-risk drinking situations and drinking cues (i.e., things they liked and did not like about drinking). The patient was also asked to fill out drinking diary cards between visits to more accurately assess their current drinking level. The follow-up phone calls reinforced the drinking limits set at each visit, challenges they faced in cutting down on drinking, and offering continued support.

Participants received a health booklet on general health issues and participated in follow-up phone calls at 6 and 12 months. Clinicians were instructed to address any health concerns in their usual manner.

<td>Haug, 2016140</td>
<td>Adolescents IG1</td>
<td>Upon completion of the baseline assessment, participants received web-based personalized feedback regarding: number of drinks consumed per week in relation to the age and gender-specific reference group; financial costs of drinking; calories consumed with alcoholic drinks; number of risking single drinking occasions in relation to the age- and gender-specific reference group. Participants also received individually tailored text messages provided over the 3-month intervention period. On the first level, the content and number of text messages were tailored according to baseline drinking patterns. Participants were assigned to 1 of 3 risk groups according to their baseline drinking patterns: (a) low risk: No RSOD occasions during the preceding 30 days and ≤14 (7 for girls) standard drinks consumed during a typical week, (b) medium risk: 1 or 2 RSOD occasions during the preceding 30 days or no RSOD occasions during the preceding 30 days and ≤14 (7 for girls) standard drinks consumed during a typical week, and (c) high risk: &gt; 2 RSOD occasions during the preceding 30 days. On the second level, the content of the text messages was tailored according to individual values for the following baseline variables: sex, motivation to reduce alcohol consumption, alcohol-related problems, typical drinking day and time, estimated peak blood alcohol concentration during the preceding 30 days, positive outcome expectancies, typical drinking situations, strategies to resist alcohol in different contexts.</td>

<td>drinking situations, and assessment location. Text messages for the medium risk group focused on: motivation to drink within low risk limits, using individual data concerning positive outcome expectancies derived from a list; alcohol-related problems, established using individual data on previous alcohol-related problems; estimated peak BAC and related risk calculated using data concerning sex, body weight, and maximum number of drinks consumed on a single occasion in the preceding month; strategies to resist alcohol in different drinking situations, established using data concerning individual drinking situations and chosen strategies for resisting alcohol. Participants in the medium- and high-risk groups received 2 text messages per week from the content categories described above. Additionally, they received information regarding local outpatient alcohol counseling services according to assessment location. Irrespective of risk group, three short message service (SMS) text message assessments were performed during the intervention period: (a) An SMS quiz on the metabolism of alcohol, for which participants received immediate individualized feedback on their answers, and if they did not respond within 48 hr, they were sent the correct response. (b) A message contest that required participants to create a text message to motivate other participants to drink within low-risk limits. The best text message was sent anonymously to all other participants after 48 hr. (c) An SMS assessment of RSOD within the preceding week, which included immediate individualized feedback. Participants in the medium- and high-risk groups received 27 text messages (1 welcome message, 3 assessment messages, 22 tailored feedback messages, and 1 goodbye message).</td>

<td>Participants received PCP-delivered standard care comprising information and brief advice about the risks associated with alcohol misuse and suggestions to decrease alcohol use. Participants also received a letter informing them of recommended drinking limits and a description of standard drinks. At 3, 6 and 9 months following baseline assessment and standard care, participants received the telephone care management (TCM) intervention. TCM included elements of motivational enhancement, decisional balance, education about alcohol misuse, and development of an individualized behavior change plan. Behavioral health specialists, 2 nurses trained in motivational approaches to substance use and brief intervention for addictions, maintained regularly scheduled phone contact to develop a treatment plan, monitor treatment effectiveness, and adverse effects, assess and encourage treatment adherence, and offer support and education. The content of individual sessions included alcohol use monitoring, support and education, and individualized education about at-risk drinking and information about common comorbidities (e.g., depressive symptoms). The TCM manual also included the use of a telephone-adapted addiction management algorithm that provided guidelines for clinical decision making regarding referral to specialty addictions treatment when needed (e.g., following a significant increase in alcohol use) and close collaboration with the patient’s PCP. Workbooks logging treatment goals and progress were mailed to participants after each session. The behavioral health specialists also had access to consultation and supervision with a psychiatrist.</td>

<td>Hilbink, 2012177</td>
<td>Adults</td>
<td>IG1</td>
<td>The intervention was comprised of 9 activities, which combined professional, organizational, and patient-directed interventions. Professional-directed interventions focused on training the general practice team and consisted of the distribution of a guideline on problematic alcohol consumption, a reminder card with signs, symptoms and patient characteristics associated with excessive alcohol consumption to be displayed on the desk of the GP, and small-scale educational training sessions (1-3 sessions, 2-3 hours per session, 10 participants max). Organizational-directed interventions further focused on training the general practice team, and included a feedback report about the proportion of patients with excessive drinking habits (participants divided into 4 categories according to the AUDIT), facilitation of the cooperation with local addiction services for support and referral, and outreach visits by a trained facilitator tailored to the needs of the practice (1-3 visits, 1 hour per visit). Patient-directed interventions consisted of GPs distribution of informational letters, leaflets and self-help books to their patients, an informational poster in the waiting room, which drew the attention to alcohol with the advice to contact the GP or look at the websites for further information, and mailed personalized feedback letters, which cited the category the patient belonged and the corresponding advice. The advice was to consult their GP or to look at websites of the National Institute for Health Promotion and Disease Prevention or Trimbos Institute. This advice was not given to patients in category 1 (safe-to-moderate drinkers). For participants in category 4 (possible dependent drinkers), the advice to inquire at a local addiction center was added.</td>

<td>Kaner, 2013(^{178}) Screening and Intervention Programme for Sensible drinking (SIPS)</td>
<td>Adults</td>
<td>IG1</td>
<td>Participants received feedback on screening plus five minutes of structured brief advice from practice staff using the SIPS Brief Advice tool 'Brief advice about alcohol risk'. The SIPS tool was based on the 'How much is too much? Simple Structured Advice intervention tool' developed as part of the UK version of the Drink-Less brief intervention program. Participants were provided with specific details about the health and social consequences of hazardous and harmful drinking, were shown a sex-specific graph, which indicated that their drinking exceeded that of most of the population, and a list of benefits that could result from reduced drinking. Thereafter patients were taken through a menu of techniques to help reduce drinking and asked to consider a personal target for an achievable reduction in drinking. At the end of the brief advice session, participants received a patient information leaflet, the Department of Health's 'How much is too much? Drinking and you', which contained details of the Drinkline telephone number where the patient could access further information including treatment options for alcohol problems. A sticker with local alcohol services was attached to the back cover.</td>

<td>LaBrie, 2009[151]</td>
<td>Young adults</td>
<td>IG1</td>
<td>Participants took part in a single session consisting of TLFB, group discussion regarding alcohol expectancies (&quot;good things&quot; and &quot;not so good things&quot; about drinking) and the role social expectancies play in alcohol consumption. In addition, the session included normative feedback, which presented the average level of drinking for women at the university. Inherent physiological differences between men and women were discussed, along with blood alcohol content levels with corresponding effects. Each participant was given a personalized blood alcohol content card. Symptoms of alcohol poisoning and information for local resources were provided. Participants discussed women's specific reasons for drinking with a focus on social and relational reasons for drinking. As a group, participants generated reasons for drinking less and reasons against drinking less and wrote down their personal reasons for change. Finally, participants set a behavioral goal indicating their intentions about drinking over the next 30 days and reported on the importance of the goal and their confidence in achieving it.</td>

<td>LaBrie, 2013</td>
<td>Young adults</td>
<td>IG1</td>
<td>The Web-BASICS feedback contained a total of twenty-six pages of interactive comprehensive motivational information based on assessment results, modeled from the efficacious in-person BASICS intervention. It addressed quantity and frequency of alcohol use, past month peak alcohol consumption, estimated blood alcohol content (BAC), and provided information regarding standard drink size, how alcohol affects men and women differently, oxidation, alcohol effects, reported alcohol-related experiences, estimated calories and financial costs based on reported weekly use, estimated level of tolerance, risks based on family history, risks for alcohol problems, and tips for reducing risks while drinking as well as alternatives to drinking. The feedback also included PNF utilizing typical student drinking norms. Participants were given the option to click links throughout the feedback to obtain additional information on standard drink size, sex differences and alcohol use, oxidation, biphasic tips, hangovers, alcohol costs, tolerance, and protective factors, as well as provided with a link to a BAC calculator. Participants were given the option to print their feedback.</td>
<td>Web-based</td>
<td>PNF</td>
<td>The generic control feedback contained three pages of information in text and bar graph format. Separate graphs, each including two bars, were used to present information regarding the number of hours spent texting, number of hours spent downloading music, and number of hours spent playing video games per week for (a) one’s own behavior, and (b) actual college student behavior. Participants were also provided with their percentile rank comparing them with other students on their respective campus (e.g., “Your percentile rank is 60%, this means that you text as much or more than 60% of other college students on your campus”).</td>

<td></td>
<td></td>
<td>web-based assessment. The feedback included each participant’s current drinking behavior, their percentile ranks in comparison with the campus average (and the percentage of students who didn’t drink in a typical month), estimated peak and typical blood alcohol levels, and the effects of alcohol at different blood alcohol levels. Feedback also included a comparison of each participant’s perceived descriptive norms with actual campus drinking rates, their alcohol outcome expectancies with embedded text indicating that many social effects of alcohol are influenced by placebo effects, feedback regarding negative consequences of drinking the participant had reported in a number of domains (i.e., alcohol and sex, alcohol and weight), and specific protective behaviors the participant was already engaging in as well as those they could initiate. Feedback content and style were similar to the Brief Alcohol Screening and Intervention for College Students (BASICS) program. Participants then received 10 weekly postcards with additional information they could use to avoid drinking-related negative consequences. Postcard tips expanded on personalized feedback topics by providing information about calculating blood alcohol levels on the basis of weight, sex, and number of drinks per hour, protective behaviors students could use (such as setting limits, alternating alcoholic with nonalcoholic beverages, and choosing not to drink), reasons why students might choose not to drink (both general and situation specific), and additional tips about avoiding negative consequences associated with alcohol use at parties, alcohol and sexual behavior, and alcohol poisoning incidents. Each postcard also included accurate information about the campus descriptive norm (i.e., 85% of students had 0, 1, 2, 3, or at most 4 drinks when they partied), and 1 postcard specifically highlighted the percentage of students on campus (more than 25%) who never drank alcohol.</td>

<td>Participants received a 30-45 min motivational enhancement (ME) session that used empathy, reflective listening and other techniques to enhance participants’ motivation to change their alcohol use and focused on delivery of feedback of baseline assessment data and setting alcohol use goals. The interventionist used techniques designed to encourage participants to elaborate or discuss their thoughts related to alcohol use and its consequences and gave participants freedom and time to discuss and select drinking goals. Participants then received two 15-20 min booster sessions scheduled 2 and 6 weeks following the initial ME session. The booster sessions provided a formal check-up on the participant's progress toward achieving the alcohol use goals articulated in the initial ME session and helped the participant make any necessary adjustments if problems had been experienced in working toward achieving the goals, or to modify the goals themselves. Participants were provided with a booklet for reference titled &quot;Is it time for a change? Is alcohol harming you?&quot;, which contained basic information about the physical psychological and social effects of alcohol, with emphasis on alcohol-related problems. The booklet then described the concept of &quot;sensible drinking&quot; and its relationship to the individual alcohol consumption goal that emerged from the participant’s ME session.</td>
<td>Individual face-to-face sessions</td>
<td>ME</td>
<td>Participants’ physicians received selected feedback from screening and baseline assessments, including AUDIT score, if positive; alcohol consumption, if in the &quot;high risk&quot; range; systolic blood pressure if ≥200; diastolic blood pressure if ≥110; GGT levels at least five times higher than normal; and blood glucose if ≥3500. Participants did not receive any systematic intervention for their alcohol use from project staff, but their physicians were not discouraged from doing so. Physicians did not receive any instructions about use of interventions for participant’s alcohol use.</td>

<td>elaboration on the information that was delivered, either by the interventionist or, through the use of techniques to limit their comments to direct questions, by the participants. Participants were provided with a booklet for reference titled &quot;Is it time for a change? Is alcohol harming you?&quot;, which contained basic information about the physical psychological and social effects of alcohol, with emphasis on alcohol-related problems. The booklet then described the concept of &quot;sensible drinking&quot; and its relationship to the individual alcohol consumption goal that emerged from the participant's BA session. Winter of 1st year: Participants were contacted to schedule an appointment for the feedback interview and provided with alcohol consumption monitoring cards to keep track of their drinking on a daily basis for 2 weeks prior to their interview. In the feedback session, interviewers reviewed participants' alcohol self-monitoring cards, and provided individualized feedback about their drinking patterns, risks, and beliefs about alcohol effects. Students' self-reported drinking rates were compared with college averages, and perceived risks for current and future problems (grades, blackouts, and accidents) were identified. Beliefs about real and imagined alcohol effects were addressed through discussions of placebo effects and the nonspecific effects of alcohol on social behavior. Biphasic effects of alcohol were described and the students were encouraged to question the assumption that &quot;more alcohol is better.&quot; Suggestions for risk reduction were outlined. Each participant left the interview with a personalized summary feedback sheet (comparing his/her responses with college norms and listing individualized problems and risk factors), along with a generic tips page describing biphasic responses to alcohol, placebo effects, and suggestions for techniques of reduced risk drinking. Winter of 2nd year: Participants were mailed graphic personalized feedback pertaining to their reports of drinking at baseline and 6- and 12-month follow-ups. Each feedback sheet contained individualized bar graphs depicting baseline and subsequent levels of drinking quantity, drinking</td>

<td>Participants received a 20-min Peer Network Counseling intervention guided by five key motivational interviewing (MI) clinical issues: rapport, acceptance, collaboration, reflections, and non-confrontation. Therapists used baseline data from participants' screening surveys to show graphic displays of substance use and peer network characteristics during the counseling session. The intervention followed Motivational Enhancement procedures with age-matched substance use normative data presented as feedback. The intervention was structured into four component parts each lasting for 5 minutes: (a) rapport building and laptop presentation of substance use feedback in simple graphic form, (b) discussion of substance use likes/dislikes and discrepancies, (c) introduction of peer network information and graphical feedback, and (d) summary, change talk, and plans. The rapport building and feedback component was used to establish a non-judgmental relationship and to present the participant with a graphical display of their substance use compared with national normative data. During the likes/dislikes discussion, participants' baseline responses are then reflected back to the teen, highlighting goals and values in order to have the participant identify and articulate discrepancies between current use and future goals and values. The peer network component began by introducing the concept of peer network and its influence on health using the laptop to illustrate the concept. The participants' peer network is reviewed for risks, protection, support, prosocial activities, and encouragement for healthful behavior as well as for substance use, influence/offers to use substance, and risky/dangerous activities. Participants were</td>

| Moore, 2010<sup>102</sup>  
Healthy Living As You Age (HLAYA) | Older adults | IG1 | Participants received a personalized feedback report and drinking diary, as well as a physician-delivered personalized feedback session guided by the report. The report outlined participants’ alcohol-related risks identified by the CARET (quantity/frequency of drinking, episodic heavy drinking, driving after drinking, others’ concern about drinking, medical/psychiatric conditions, symptoms that could be worsened by drinking, medications that could interact with or be diminished by alcohol,) and potential consequences (e.g., increased sedation and falls). The physician gave the participant oral and written advice (in prescription-style format on an alcohol and aging education booklet). Participants received up to three calls delivered by a health educator (HE) at 2, 4, and 8 weeks after baseline visit. During the first call, the HE reviewed and discussed risks associated with drinking, and used principles of motivational interview to facilitate behavioral change. The content of the booklet given to participants at baseline was discussed, providing opportunities to learn more about specific risks. Participants’ drinking patterns, reasons for alcohol consumption, and details regarding any previous attempts to quit were assessed. At the end of the call, the HE asked about participants’ intentions to reduce alcohol use, and encouraged them to develop a drinking agreement. If a drinking agreement was completed during the first (40 min) call, it was reviewed during the second and third (20 min) telephone calls. If no drinking agreement was completed, during the remaining calls, the HE reiterated the benefits of reducing alcohol use and discussed potential problems associated with initiating behavioral changes. | Individual face-to-face sessions, telephone calls | MI, PHF | Participants received a booklet outlining recommended behaviors for alcohol use, nutrition, exercise, medication use and smoking. Research assistants encouraged participants to read the booklet and discuss it with their PCPs. |

<td>Upon completion of the computerized baseline assessment, participants received a personalized feedback printout. The format of the feedback was modeled after the normative component of the BASICS interview. The feedback included a summary of the participant's perceived drinking norms compared with actual drinking norms and a summary of participants' reported consumption compared with average college drinking behavior. Additionally, participants' percentile ranking, comparing their drinking with other college students drinking, was provided. Actual norms were based on data collected on the same campus in the previous year from a large sample of randomly selected undergraduate students participating in the Motivating Campus Change (MC2) project. The feedback was designed to communicate three things: (a) &quot;This is how much you drink,&quot; (b) &quot;This is how much you think the typical student drinks,&quot; and (c) &quot;This is how much the typical student actually drinks.&quot;</td>

<td>Immediately following assessment, participants received gender-specific web-based personalized normative feedback (PNF) based on the participants' screening results. The intervention was developed on the basis of the normative feedback component of the Brief Alcohol Screening and Intervention for College Students (BASICS) intervention. Following the conceptualization of PNF as personalized information designed to correct overestimated normative perceptions, this intervention was extremely brief and contained only three required elements, which included information regarding (a) one's own drinking behavior, (b) one's perceptions of other same-sex students' drinking behavior on the participating campus, and (c) other same-sex students' self-reported drinking behavior in text and bar graph formats. Together, these three pieces of information explicitly illustrated that participants overestimated the prevalence of drinking among their same-sex peers and, for participants who reported heavy drinking, that most same-sex students drank less than the participant did. Bar graphs were provided for weekly frequency and number of drinks consumed per week. Each graph included three bars representing the campus norm (specific to participant's gender), the participants' reported perception of the campus norm, and the participants' reported behavior. Normative feedback about episodic heavy drinking was not provided.</td>

<td>Upon completion of the computer-based assessment, participants were directed to the intervention software. The goal of the software was to facilitate reductions in alcohol use via a single 20-min intervention session following motivational interviewing principles, as well as the FRAMES brief intervention model with use of synchronous interactivity, user input and empathic reflection. A mobile three-dimensional cartoon character capable of over 50 specific animated actions did the 'talking' for the entire program. This character read each item for the participant, acted as narrator and guide throughout the process, and actively sought a non-judgmental, empathic and non-threatening demeanor using reflections and self-deprecating humor. The experience of working with the software was intended to be highly interactive, with immediate responses to most input, occasional summaries, branching based on participant preferences. Participants were asked a number of questions about their preferences in music and television, were shown brief video clips consistent with their preferences, and were asked to provide feedback regarding their opinion of the various video clips.</td>

<td>IG1</td>
<td>Participants received one 30 min motivational interviewing session guided by Self-determination theory (SDT), which postulates that motivation to perform a behavior increases when three basic psychological needs are satisfied—the need for autonomy (developing discrepancy, rolling with resistance), the need for competence (supporting self-efficacy), and the need for relatedness (establishing empathy). In addressing the need for relatedness, the researcher discussed with the participant in a respectful caring manner, her goals for her pregnancy, as well as her beliefs and attitudes about prenatal alcohol use. Participants also received feedback regarding alcohol use obtained in the initial assessment, which the researcher provided in a non-judgmental way. In addressing the need for autonomy, the researcher engaged the participant in simple and complex reflections, open-ended questions, and summarizations to assist the participant in developing increased awareness of any incongruence between her goals for the pregnancy and her current drinking behaviors. If met with resistance due to the participant's ambivalence between current behaviors and changes needed to meet pregnancy goals, the researcher, with participant permission, provided neutral information and direction to assist the participant in development of strategies for behavior change. In addressing the need for competence, the researcher supported the participant with respect and acceptance of the participant as capable of making healthy decisions for herself.</td>

<td>Pregnant women</td>
<td>IG1</td>
<td>The intervention was developed using Social Cognitive Theory, which comprises components including goal setting, self-monitoring, perceived self-efficacy, negative outcome expectancies of drinking, positive outcome expectancies of cessation, and skills for cessation. The intervention included a 10 min educational session coupled with a nine-step self-help manual to be completed by participants at home in 9 days. During the education session, an educator described the effects of alcohol on the fetus and explained the use of the manual, which participants then completed the manual at home. Each step in the manual targeted a behavior or cognition that would enhance the likelihood of cessation. Exercises were included to stimulate thought about key ideas, to build alcohol cessation skills, and to provide practice related to those skills. The content of the steps in the manual included: (1) FAS information: increasing motivation to quit; (2) building self-efficacy to quit; (3) identifying the participant's drinking pattern using a diary; (4) removing alcohol and avoiding drinking locations; (5) finding a buddy and engaging in social support; (6) self-monitoring and self-reward for quitting; (7) resisting interpersonal and media pressure to drink; (8) coping with stress without drinking; and (9) maintaining abstinence. Participants were called one week after counseling session to assess their progress and answer questions about the self-help manual.</td>

<td>Participants received Alcohol Screen, a physician-delivered structured behavioral change program. This consisted of five short consultations (introduction, patient education and three follow-up visits) designed to reduce drinking to limits recommended by the National Health and Medical Research Council (NHMRC) of 28 or fewer drinks per week for men and 14 or fewer for women. Alcoholscreen was adapted from the Smokescreen and DRAMS programs for GPs. At the first visit, the GP invited the participant to join the study, provided a self-help manual (&quot;A Guide to Healthier Drinking&quot;) and recommended certain sections to be read during the following week. Participants were instructed to use day diary for monitoring alcohol consumption during the following week. At the second visit, lasting 15-20 min, a personalized approach to patient education regarding the harmful effects of excessive alcohol consumption was employed using a flip-over display unit. This consisted of 12 pictorial and text prompts to raise the participant's level of awareness of</td>

<td>alcohol-related problems. Participant counseling included motivational interviewing techniques in which the &quot;good things&quot; about heavy drinking were weighed against the &quot;bad things&quot;, prompting the participant to make a personal decision to reduce drinking. Information was provided about recommended daily and weekly limits, problems associated with excessive drinking, identification of high-risk situations, instructions on coping with high-risk situations without heavy drinking, discussion of alternatives associated with a changed lifestyle, and other advice on relapse prevention. The participant’s consumption level was compared with Australian drinking norms and the drinking pattern was analyzed using information recorded in the drinking diary. Participants had follow up visits 1, 3, and 5 months later aimed at encouraging and supporting new drinking habits. Goals and drinking decisions were reviewed and reasons for lapses analyzed, and renewed motivation for cutting down was attempted when necessary. The first follow up visit was a standard consultation (lasting 5-25 min), and the remaining two were short consultations lasting 5 min or less.</td>

<td>assistant, and one nurse practitioner) within the university health services. The intervention combined patient-centered motivational interviewing (MI) techniques and cognitive-behavioral skills training based on NIAAA curriculum “Clinical Protocols to Reduce High Risk Drinking in College Students” and the Brief Alcohol Screening and Intervention for College Students (BASICS). The MI framework included clinician empathizing, reflecting, reframing negative talk into change talk, rolling with resistance, avoiding argumentation, developing discrepancy between negative or ambivalent feelings toward alcohol, supporting self-efficacy through contemplation of past success, and acknowledging reluctance to change. A “participant feedback” document was compiled by research staff based on each participant's responses to the Healthy Lifestyle Questionnaire and TLFB, and this document was used by the providers as the source of individual normative feedback information. The participant feedback document summarized the participant's Healthy Lifestyle Questionnaire responses regarding overall healthy lifestyle behaviors (nutrition, exercise, mental health, safety, tobacco, drugs, sleep); alcohol-related harms, especially drinking and driving; alcohol expectancies; tolerance; use of protective behaviors, including choosing not to drink, counting drinks and setting limits, eating before drinking, selecting a designated driver, and avoiding drinking games and distilled spirits; and readiness-to-change. The participant feedback document also summarized the TLFB data on quantity and frequency of alcohol consumption, including number of drinking days, average and peak number of drinks per drinking day, typical and peak BAC with instructions on estimation of BAC using a BAC card, and norms clarification by comparing personal alcohol consumption with peer alcohol consumption. The focus of the first BMI session was to establish rapport between the participant and the provider. By initially focusing on the participant's expressed healthy lifestyle concern, the provider was able to gain the interest and trust of the participant, allowing for a facilitated introduction of the alcohol discussion and the start of cognitive-behavioral skills training. The second session maintained the participant-centered focus of MI and stressed the alcohol skills training components of the BASICS program. At completion of the second BMI session, participants received the participant feedback document for training in the BMI protocol and were provided an alcohol-prevention educational brochure, “Drinking: What’s Normal, What’s Not”.</td>

<td>The intervention program, called &quot;Alcohol-Everything within the Limits?!&quot;, is a web-based 3-session tailored program targeting adult problem drinking. The theoretical framework was the I-Change model, which combines different models and integrates them in pre-motivational, motivational, and post-motivational phases. Participants received personalized advice immediately following assessment, which consisted of 5 parts, each focusing on a different psychosocial construct (i.e., knowledge, awareness, attitude, social influence, self-efficacy, and action-planning). The first part of the program served as a starting point of the drinking behavior change process (pre-motivational phase) by addressing the concepts of knowledge and awareness, providing participants with information about German alcohol guidelines (not drinking more than 1 [women] or 2 [men] standard drinks per day and having at least 2 alcohol-free days a week), and assessed whether respondents were meeting this guideline by using comparative/normative feedback. In addition, participants’ scores were depicted graphically using a traffic light symbol (indicating whether they met, almost met, or did not meet the guidelines). To increase participants’ knowledge, the relationship between alcohol and various diseases was explained, and information tailored to the respondent’s health status was given about alcohol and pregnancy, and about the possible influence of participants’ drinking behavior on their children (if applicable). The second part of the program offered personalized feedback concerning the perceived pros and cons of alcohol drinking as perceived by the respondent, with the goal of creating a positive attitude toward not drinking more &gt;2/1 [MF] drinks per day. The first part explained the importance of social influence in a tailored message by focusing on the respondent’s partner, family friends, and colleagues. In the fourth part, preparatory action plans were defined to prepare the intended behavior change. The final part focused on self-efficacy and coping plans by identifying difficult situations and suggesting ways to cope with them. Personalized tips were given on how to deal with the perceived difficult situations to overcome potential barriers (post-motivational phase), and the situations and plans were summarized for individual respondents to help...</td>

<td>Upshur, 2015&lt;sup&gt;187&lt;/sup&gt; Project RENEWAL</td>
<td>Adults</td>
<td>IG1</td>
<td>The intervention consisted of: 1) providing evidence-based training and supports to the medical leadership and randomized intervention PCPs; 2) modifying the electronic medical record (EMR) to provide alcohol screening results and alcohol-specific notes for PCP and Care Manager (CM) visits; and 3) training a CM specifically designated to provide intervention participants with alcohol education materials, ongoing self-management support, linkage to formal addiction treatment services and self-help groups, and wellness counseling and goal setting. The PCP training included 8 hours in 5 didactic sessions on the chronic care model, using the modified EMR module for documenting problem alcohol use and intervention strategies (e.g. brief motivational intervention, education materials, drinking reduction goal setting, wellness goals, referrals to formal substance abuse services, referrals to the clinic's mental health services), interpreting the screening measure, completing a brief alcohol intervention as described in the NIAAA Clinician's Guide, review of pharmacological treatments for alcohol addiction, motivational interviewing training, and working with the CM. A 15-page “Intervention Provider Manual” synthesized the recommended treatment steps for the PCPs and was provided to each. Two sessions were held prior to the study starting and 3 additional booster and review sessions were provided over the subsequent year. Intensive CM training (20 hours) was provided based on a study-developed CM treatment manual. The training included: information on the CM role for the study; collaborating with the PCPs; using the documentation templates in the EMR; assessing baseline history and services needs; motivational interviewing techniques; delivering trauma-informed care; the patient follow-up schedule; a structured format for each follow-up visit; patient education materials on safe alcohol consumption for women, problem alcohol use consequences for women, self-management goal setting; and up-to-date lists of local addiction services and AA groups that patients could be referred to. Intervention patients received the guideline-based PCP brief intervention for problem alcohol use and referral to the CM for ongoing follow-up visits for 6 months. It was expected that PCPs would provide 4–6 appointments.</td>
<td>Individual face-to-face sessions, telephone calls</td>
<td>General counseling, MI</td>
<td>Usual care patients did not receive referrals to, or outreach from, the study-trained CM and their PCPs were not provided any alcohol intervention training or patient materials. They delivered usual care for medical conditions, including any behavioral health or drug or alcohol use problems. All usual care participants had unrestricted access and use of all primary care and specialty care offered by the clinic, including mental health services (counseling and psychiatry); dental and vision services; laboratory and radiology; pharmacy; ob/gyn; medical respite care; hospital admissions; and general case management for benefits, employment, housing, transportation, and legal issues.</td>

<td>Pregnant women</td>
<td>IG1</td>
<td>The health-counseling intervention consisted of 7 steps addressed in 3 feedback sessions. The intervention was based on the I-Change model, which distinguishes 3 phases of health behavior change (awareness, motivation, and action). Feedback Session 1, approximately 2 weeks after baseline assessment, consisted of 5 steps taking approximately 10 minutes of the initial consultation. In step 1, the midwife assessed the amount and frequency of alcohol use of the participant before and during pregnancy, of her partner during pregnancy, and the participant's motivation to stop drinking alcohol. In step 2, participants strongly motivated to stop alcohol consumption during pregnancy were prompted to state the advantages of abstinence. Moderately or not motivated participants were asked to report on their perceived disadvantages of drinking during pregnancy. The midwife then advised them to stop drinking alcohol. In step 3, the barriers for successful abstinence and the mobilization of social support were discussed. In step 4, a self-help guide, adapted from an intervention on smoking in pregnancy, and relevant websites were mentioned. The midwife stimulated the participant to develop action plans for abstinence and coping with problems they might encounter when trying not to drink alcohol. If appropriate, access to alcohol addiction services was discussed. In step 5, participants were asked to set a date for stopping their alcohol use. Feedback session 2, approximately 8 weeks after baseline, consisted of step 6, which was addressed in approximately 1 minute. In this step, midwives again assessed the alcohol use of the participant and asked her if she needed additional support for not drinking alcohol. Feedback session 3, approximately 14 weeks after baseline, consisted of step 7, which was also addressed in approximately 1 minute. In this step, midwives discussed alcohol use and its implications for breastfeeding.</td>
<td>Individual face-to-face sessions</td>

<td>Pregnant women</td>
<td>IG2</td>
<td>Participants received usual care from their midwife (recommended complete alcohol abstinence) and computer-tailored feedback via the Internet, which was iterative and item based. The intervention was based on the I-Change model. The intervention consisted of 7 steps addressed in 3 feedback sessions. The intervention was based on the I-Change model, which distinguishes 3 phases of health behavior change (awareness, motivation, and action). Feedback 1, given immediately after baseline consisted of 4-5 pages. This feedback was tailored to several participant characteristics assessed in the baseline questionnaire (alcohol use, knowledge, risk perception, attitude, social influence, self-efficacy, intention, and action and coping plans. The first feedback letter contained the recommendation of complete alcohol abstinence during pregnancy and information on the possible consequences of prenatal alcohol use and the associated risk factors. In addition, participants received feedback on their risk perception of prenatal alcohol use; perceived social influence (not) to drink during pregnancy; self-efficacy to refrain from prenatal alcohol use in specific situations, including suggestions on how to cope with these situations; the extent to which participants were planning to undertake specific actions to abstain from prenatal alcohol use; and how to cope with certain difficult situations, including the formulation of personal plans in the shape of if-then statements. The second feedback letter, 6 weeks after baseline, included personalized information on the participants’ choice of characteristics assessed with the baseline questionnaire (e.g., risk perception or attitude). Depending on the number of characteristics chosen by the participant, this feedback consisted of 1 or 2 pages. The third feedback letter, given immediately after T1, consisted of 3 to 4 pages of ipsative feedback tailored to changes in the respondent characteristics assessed at T1 in comparison to the baseline questionnaire. Feedback letters were visible on the computer screen and also sent to the respondent by email.</td>

<td>What Do You Drink (WDYD)</td>
<td>Adults</td>
<td>IG1</td>
<td>guidelines of the Dutch National Health Council, recommending against drinking &gt;2/1 [M/F] drinks per day; (2) the drinks participants consumed in the past year, with estimates of the number of calories consumed; the amount of weight added because of drinking, and the amount of money spent on drinking; and (3) a bar chart comparing the number of drinks per week that participants' same-sex peers actually consumed. After receiving PF, participants were offered access to the second part of the intervention via a registration and sign-up procedure. The second part of WDYD focused on the action phase of the behavior change process with a general goal of reducing heavy drinking. Participants were prompted to make decisions about the maximum number of drinks they wanted to consume on every day of the week at a given point in time, preferably within the limits of low-risk drinking. WDYD also focused on strengthening participants' drinking refusal self-efficacy by providing tips to resist alcohol in different drinking situations. Participants were asked to choose three out of the twelve provided drinking situations and were then asked to give a rationale why they found it hard to resist alcohol in the three chosen situations. Tips were offered for each of the chosen drinking situations to help participants cope with those situations in order to succeed and maintain drinking goals.</td>

<tr>
<td>Wallace, 1988188</td>
<td>Adults</td>
<td>IG1</td>
<td>After assessment interview with GP, participants were shown a histogram based on figures from a national survey of drinking habits to illustrate how their weekly consumption compared with that of the general population. Participants received advice about the potential harmful effects of their current level of alcohol consumption, as well as the information booklet &quot;That's the Limit.&quot; Participants were advised not to drink more than 18/9 [M/F] units per week. Where there was evidence of dependence on alcohol, GPs were encouraged to advise abstinence. Participants were given a drinking diary, the front cover of which was a facsimile of an EC10 prescription with the words &quot;Cut Down on your Drinking!&quot; The last page contained a guide to the alcohol content (in units) of a range of drinks. Participants were offered an initial follow up appointment one month later and subsequent appointments at 4, 7, and 10 months were at the discretion of the GP. During the follow up sessions, the participant's drinking diary was reviewed and feedback given</td>
<td>Individual face-to-face sessions</td>
<td>PNF, PHF</td>
<td>Participants were given brief general health advice and booklet on heart disease. They received no advice from their GP about drinking except at their own request or if there was evidence that their alcohol consumption had already resulted in substantially impaired liver function (GGT &gt;150 IUL).</td>

<td>Older adults</td>
<td>IG1</td>
<td>The intervention included a population-based management approach, measurement-based care, and integration of addiction expertise through a RAND-based clinical psychologist affiliated with the Motivational Interviewing Network of Trainers. Along with therapy, participants had the option to use medication-assisted treatment (MAT) with sublingual buprenorphine/naloxone for opioid use or long-acting injectable naltrexone for alcohol use disorders. Care coordinators met with participants and encouraged them to meet with a therapist for evaluation and treatment planning. All participants were entered into a registry that tracked treatment progress and prompted care coordinators to reach out to patients with missed visits. Care coordinators conducted regular assessments of substance use; results were entered into the registry and reviewed during team meetings.</td>
<td>Individual face-to-face sessions</td>
<td>ME, PNF, Referral, SC</td>
<td>Minimal intervention consisted of a 5-minute brief advice intervention with the practice or research nurse involved in feedback of the results of the screening and discussion regarding the health consequences of continued hazardous alcohol consumption. The participant also received a brief self-help booklet “Safer Drinking - a self help guide,” outlining the consequences of excessive alcohol consumption and providing information on sources of help for drinking problems locally and nationally.</td>

<td>Wilson, 2014¹⁸⁹</td>
<td>Adults</td>
<td>IG1</td>
<td>Participants received a 5-min structured advice session on their baseline alcohol consumption, tailored to their physical comorbidity. The brief advice consisted of personalized, structured feedback to participants about their level of alcohol-related risk or harm, a visual normative comparison of their drinking behavior in relation to population norms, health benefits associated with reducing alcohol consumption from their current levels, and practical suggestions on how to reduce drinking levels. The nurse contacted the participant and a short telephone assessment was made regarding the participant's alcohol consumption in the previous 4 weeks using the extended AUDIT-C. If the participant was still consuming alcohol at hazardous levels, a referral was made to Step 3. Step 3 consisted of a referral to the local specialist alcohol services to receive specialist intervention, including, as necessary: detoxification, inpatient care, outpatient counselling, group therapy, relapse prevention treatment or medication. There was no limit on the intensity or duration of Step 3.</td>
<td>Individual face-to-face sessions</td>
<td>PNF</td>
<td>Participants received an advice leaflet produced by the British Heart Foundation (hypertension trial).</td>

<tr>
<td>NCT01881841</td>
<td>Computer Adaptation of Screening, Brief MET Intervention to Reduce Teen Drinking</td>
<td>US</td>
<td>150</td>
<td>The goal of this project is to evaluate the feasibility, acceptability, and effect size of a new computerized Motivational Enhancement Therapy (cMET) intervention for alcohol-involved adolescents in primary care.</td>
<td>Ongoing: Est. Completion Date Aug 2017</td>
</tr>
<tr>
<td>NCT02642757</td>
<td>Alcohol Brief Counseling in Primary Care</td>
<td>Chile</td>
<td>262</td>
<td>This study evaluates the effectiveness of a brief intervention for the reduction of alcohol use among risky alcohol users in primary care delivered by paramedics.</td>
<td>Completed. No published results yet.</td>
</tr>
<tr>
<td>NCT02860442</td>
<td>Project Guard: Reducing Alcohol Misuse/Abuse in the National Guard</td>
<td>US</td>
<td>750</td>
<td>The overall goal for the study is to test the efficacy of a smartphone app which includes an alcohol brief intervention (SP-BI) versus an Enhanced Usual Care (EUC) condition for National Guard members in the State of Ohio who meet criteria for at-risk drinking in the previous 3 months.</td>
<td>Ongoing: Est. Completion Date Jun 2020</td>
</tr>
<tr>
<td>NCT02671019</td>
<td>Effectiveness and Costs of Internet-based Treatment for Harmful Alcohol Use and Face-to-face Treatment in Addiction Care</td>
<td>Sweden</td>
<td>350</td>
<td>The purpose of this trial is to compare the effectiveness and costs of a five-module Internet-based treatment program (including therapist support) for harmful alcohol use with the effectiveness and cost of the same treatment content delivered face-to-face in specialized addiction treatment.</td>
<td>Ongoing: Est. Completion Date Nov 2019</td>
</tr>
<tr>
<td>NCT02645721</td>
<td>Internet Based Cognitive Behavior Treatment for Alcohol Use Disorders (ICBT-AUD)</td>
<td>Sweden</td>
<td>166</td>
<td>The purpose of this study is to determine whether extensive internet based cognitive behavior treatment program with guidance is a more effective method to treat individuals with alcohol use disorders than a briefer cognitive behavior treatment program without guidance.</td>
<td>Ongoing: Est. Completion Date Jun 2019</td>
</tr>
<tr>
<td>NCT02703116</td>
<td>Reducing Hazardous Alcohol Use in Social Networks Using Targeted Intervention</td>
<td>US</td>
<td>450</td>
<td>The purpose of this study is to assess the feasibility, acceptability and test the initial efficacy of eSBI compared with a nutrition intervention for at-risk youth.</td>
<td>Ongoing: Est. Completion Date Jul 2019</td>
</tr>

<tbody>
<tr>
<td>NCT01797835</td>
<td>Alcohol Screening in an Ethnically Diverse Sample of Adolescents in Primary Care</td>
<td>US</td>
<td>1573</td>
<td>The current study tests the new NIAAA screening guide questions, which ask about friend and adolescent drinking, to see how well these questions work to predict subsequent alcohol use, problems, and involvement in other risk behaviors, such as sexual risk-taking and delinquency. In addition, the investigators plan to provide a brief motivational intervention for some at-risk teens and see whether alcohol use differs for those teens who receive the intervention and those teens who receive enhanced usual care.</td>
<td>Ongoing: Est. Completion Date Aug 2018</td>
</tr>
<tr>
<td>NCT02584621</td>
<td>Web-Based Adolescent Motivational Enhancement Study (Web-AME)</td>
<td>US</td>
<td>150</td>
<td>This study is a randomized controlled trial that compares the effectiveness of an electronic personalized health screening app incorporating motivational feedback (i.e. &quot;Check Yourself&quot;) to usual care among moderate to high risk alcohol users.</td>
<td>Ongoing: Est. Completion Date Feb 2017, no published results yet</td>
</tr>
<tr>
<td>NCT02337361</td>
<td>Computerized Tool for Preventing Prenatal Drinking</td>
<td>US</td>
<td>200</td>
<td>The purpose of the study is to test the efficacy of an innovative, self-administered computerized screening and brief intervention (SBI) for drinking during pregnancy will be adapted for use with non-pregnant childbearing age women.</td>
<td>Ongoing: Est. Completion Date Aug 2018</td>
</tr>
<tr>
<td>NCT02187887</td>
<td>Online Program for Young Adult Veteran Drinkers</td>
<td>US</td>
<td>793</td>
<td>The primary objective of the research study is to test the feasibility of a brief Internet-based intervention to reduce heavy alcohol use among young adult veterans of wars in Iraq and Afghanistan.</td>
<td>Ongoing: Est. Completion Date Apr 2016, no published results yet</td>
</tr>
<tr>
<td>NCT02834949</td>
<td>Improving Brief Alcohol Interventions with a Behavioral Economic Supplemen</td>
<td>US</td>
<td>393</td>
<td>The purpose of this study is to evaluate the efficacy of a Substance-Free Activity Session (SFAS) as a supplement to a brief motivation intervention (BMI) in reducing alcohol use and alcohol-related consequences in college students.</td>
<td>Ongoing: Est. Completion Date Aug 2017, no published results yet</td>
</tr>
<tr>
<td>NCT01400581</td>
<td>Considering Healthier Drinking Options in Collaborative Care (CHOICE)</td>
<td>US</td>
<td>304</td>
<td>The proposed study will evaluate the effectiveness of a collaborative care intervention for evidence-based management of alcohol use disorders in primary care settings.</td>
<td>Completed. No published results yet.</td>
</tr>
<tr>
<td>NCT02978027</td>
<td>Mentored Research on Improving Alcohol Brief Interventions in Medical Settings</td>
<td>US</td>
<td>300</td>
<td>The purpose of the study is to delineate the degree to which adding motivational interviewing components to a brief intervention for unhealthy alcohol use improves outcomes.</td>
<td>Ongoing: Est. Completion Date Sep 2017, no published results yet</td>
</tr>
