IMPORTANCE Falls are the leading cause of injury-related morbidity and mortality among older adults in the US. In 2018, 27.5% of community-dwelling adults 65 years or older reported at least 1 fall in the past year and 10.2% reported a fall-related injury. In 2021, an estimated 38,742 deaths resulted from fall-related injuries.

OBJECTIVE The US Preventive Services Task Force (USPSTF) commissioned a systematic review to evaluate the effectiveness and harms of primary care–relevant interventions to prevent falls and fall-related morbidity and mortality in community-dwelling adults 65 years or older.

POPULATION Community-dwelling adults 65 years or older at increased risk of falls.

EVIDENCE ASSESSMENT The USPSTF concludes with moderate certainty that exercise interventions provide a moderate net benefit in preventing falls and fall-related morbidity in older adults at increased risk for falls. The USPSTF concludes with moderate certainty that multifactorial interventions provide a small net benefit in preventing falls and fall-related morbidity in older adults at increased risk for falls.

RECOMMENDATION The USPSTF recommends exercise interventions to prevent falls in community-dwelling adults 65 years or older who are at increased risk for falls. (B recommendation) The USPSTF recommends that clinicians individualize the decision to offer multifactorial interventions to prevent falls to community-dwelling adults 65 years or older who are at increased risk for falls. Existing evidence indicates that the overall net benefit of routinely offering multifactorial interventions to prevent falls is small. When determining whether this service is appropriate for an individual, patients and clinicians should consider the balance of benefits and harms based on the circumstances of prior falls, presence of comorbid medical conditions, and the patient’s values and preferences. (C recommendation)

See the Summary of Recommendations figure.
Preamble

The US Preventive Services Task Force (USPSTF) makes recommendations about the effectiveness of specific preventive care services for patients without obvious related signs or symptoms to improve the health of people nationwide.

It bases its recommendations on the evidence of both the benefits and harms of the service and an assessment of the balance. The USPSTF does not consider the costs of providing a service in this assessment.

The USPSTF recognizes that clinical decisions involve more considerations than evidence alone. Clinicians should understand the evidence but individualize decision-making to the specific patient or situation. Similarly, the USPSTF notes that policy and coverage decisions involve considerations in addition to the evidence of clinical benefits and harms.

The USPSTF is committed to mitigating the health inequities that prevent many people from fully benefiting from preventive services. Systemic or structural racism results in policies and practices, including health care delivery, that can lead to inequities in health. The USPSTF recognizes that race, ethnicity, and gender are all social rather than biological constructs. However, they are also often important predictors of health risk. The USPSTF is committed to helping reverse the negative impacts of systemic and structural racism, gender-based discrimination, bias, and other sources of health inequities, and their effects on health, throughout its work.

Importance

Falls are the leading cause of injury-related morbidity and mortality among older adults in the US. In 2018, 27.5% of community-dwelling adults 65 years or older reported at least one fall in the past year (714 falls per 1000 older adults) and 10.2% reported a fall-related injury (170 fall-related injuries per 1000 older adults). Native American/Alaska Native older adults reported more falls (32.2%) and fall-related injuries (15.2%) compared with other racial and ethnic groups. Stratified by age, 25.9% of adults aged 65 to 74 years reported falling and 9.3% reported fall-related injuries; 28.5% of adults aged 75 to 84 years reported falling and 10.6% reported fall-related injuries; and 33.8% of adults 85 years or older reported falling and 13.9% reported fall-related injuries. In 2021, an estimated 38,742 deaths resulted from fall-related injuries. Most fall-related deaths occur in adults 85 years or older; this group also has the fastest-growing rate of death from falls.

USPSTF Assessment of Magnitude of Net Benefit

The US Preventive Services Task Force (USPSTF) concludes with moderate certainty that exercise interventions provide a moderate net benefit in preventing falls and fall-related morbidity in older adults at increased risk for falls.

The USPSTF concludes with moderate certainty that multifactorial interventions provide a small net benefit in preventing falls and fall-related morbidity in older adults at increased risk for falls.

See Table 1 for more information on the USPSTF recommendation rationale and assessment and the eFigure in the Supplement for information on the recommendation grade. See the Figure for a summary of the recommendation for clinicians. For more details on the methods the USPSTF uses to determine the net benefit, see the USPSTF Procedure Manual.3
The following interventions were reviewed by the USPSTF but lack sufficient evidence to assess their benefits and harms in preventing falls in community-dwelling older adults when offered alone and not in the context of a multifactorial intervention: environmental modification, medication management, psychological interventions, education, and combination interventions (exercise plus environment interventions or exercise plus education interventions).4

**Additional Tools and Resources**

The Centers for Disease Control and Prevention (CDC) has guides on fall prevention interventions (https://www.cdc.gov/falls/programs/index.html).

The CDC STEADI (Stopping Elderly Accidents, Death, and Injuries) initiative helps reduce fall risk among older patients (https://www.cdc.gov/steadi/index.html).

**Other Related USPSTF Recommendations**

The USPSTF recommends screening for osteoporosis with bone measurement testing to prevent osteoporotic fractures in women 65 years or older and in postmenopausal women younger than 65 years who are at increased risk of osteoporosis.8 The USPSTF also recommends against daily supplementation with 400 IU or less of vitamin D and 1000 mg or less of calcium for the primary prevention of fractures in postmenopausal women. The USPSTF has concluded that the evidence is insufficient to assess the balance of the benefits and harms of daily supplementation with doses greater than 400 IU of vitamin D and greater than 1000 mg of calcium for the primary prevention of fractures in postmenopausal women and that the evidence is insufficient to assess the balance of the benefits and harms of vitamin D and calcium supplementation, alone or in combination, for the primary prevention of fractures in men and premenopausal women.9

**Update of Previous USPSTF Recommendation**

This recommendation replaces the 2018 USPSTF recommendation on interventions to prevent falls in community-dwelling older adults. In 2018, the USPSTF recommended exercise interventions to prevent falls in community-dwelling adults 65 years or older who are at increased risk for falls and that clinicians selectively offer multifactorial interventions to prevent falls to community-dwelling adults 65 years or older who are at increased risk for falls. The USPSTF also recommended against vitamin D supplementation to prevent falls in community-dwelling adults 65 years or older.10 The current recommendation does not address the use of vitamin D to prevent falls; this evidence will be reviewed in a separate USPSTF recommendation (in progress). This recommendation is otherwise consistent with the 2018 USPSTF recommendation.

**Supporting Evidence**

**Scope of Review**

The USPSTF commissioned a systematic evidence review on the effectiveness and harms of primary care–relevant interventions to prevent falls and fall-related morbidity and mortality in community-dwelling adults 65 years or older.410 Studies conducted solely in populations with specific medical diagnoses for which interventions could...
The USPSTF recommends exercise interventions to prevent falls in community-dwelling adults 65 years or older. The trials generally included multiple exercise components, and the exercise interventions were primarily conducted in a supervised group setting. The mean age of participants ranged from 68 years to 88 years. Additionally, the interventions were primarily conducted in a supervised group setting.

Benefits of Interventions
The USPSTF reviewed 37 trials (n = 16,117) of exercise interventions to prevent falls in community-dwelling older adults. The trials generally included multiple exercise components, and the exercise interventions were primarily conducted in a supervised group setting. The mean age of participants ranged from 68 years to 88 years.
To fulfill its mission to improve health by making evidence-based recommendations for preventive services, the USPSTF routinely highlights the most critical evidence gaps for creating actionable preventive services recommendations. The USPSTF often needs additional evidence to create the strongest recommendations for everyone and especially for persons with the greatest burden of disease. In some cases, clinical preventive services have been well studied, but there are important evidence gaps that prevent the USPSTF from making recommendations for specific interventions and for specific populations. In this table, the USPSTF summarizes the gaps in the evidence for interventions to prevent falls in community-dwelling older adults.

### Interventions to Prevent Falls in Community-Dwelling Older Adults

**Abbreviation:** USPSTF, US Preventive Services Task Force.

Twenty trials solely recruited participants at increased risk, while 15 trials included populations with anywhere from 6% to 59% of participants at increased risk for falls; 2 trials did not report the percentage of participants at increased risk. Most trials (22/37) included a history of falls as either the sole criterion or as 1 of several risk factors defining increased risk. Across the 35 trials that reported it, 58% of participants were at increased risk for falls.4,11

Most trials studying exercise interventions used multiple exercise components, including gait, balance, and functional training; strength and resistance; flexibility; tai chi/3-dimensional training; general physical activity; and endurance. Nearly all exercise interventions included gait, balance, and functional training (30/37 trials), and about two-thirds of the trials (25/37) included a strength and resistance training component.4,11

A pooled analysis of 29 trials (n = 14,475) demonstrated that exercise interventions were associated with a significant reduction in the rate of incident falls at the longest follow-up (6–24 months) (incidence rate ratio [IRR], 0.85 [95% CI, 0.75–0.96]). Pooled analyses also showed that exercise interventions reduced the number of persons experiencing 1 or more falls at the longest follow-up (6–24 months) (25 trials; n = 13,384; relative risk, 0.92 [95% CI, 0.87–0.98]) and risk of injurious falls at 6 to 60 months of follow-up (12 trials; n = 3984; IRR, 0.84 [95% CI, 0.74–0.95]). Pooled analyses found no significant reductions in fall-related fractures or all-cause mortality.4,11

The USPSTF reviewed 28 trials (n = 27,784) of multifactorial interventions to prevent falls in community-dwelling older adults. These trials included a heterogeneous group of complex assessment and intervention components. Mean age ranged from 72 years to 85 years.15 Twenty-one trials solely recruited patients at increased risk for falls according to various definitions. Nearly half of the trials (13/28) defined increased risk as having a history of falling as the sole criterion. Among the 7 remaining trials that recruited patients unselected for risk, 5 reported that 19% to 44% of those recruited were at increased risk for falls, and 2 did not report the percent of participants at increased risk. Across the 26 trials that reported it, 65% of participants were at increased risk.4,11

All trials administered an initial assessment of modifiable fall risk factors to customize the intervention for each participant. All trials assessed fall risk factors; the most commonly assessed components were functional assessments (eg, timed Up and Go test),16 environmental assessments, medication review, and vision assessments. All trials delivered individualized fall prevention advice and recommendations based on the multifactorial risk assessment. The most commonly recommended intervention components were individual or group exercise interventions, medication review, referral to vision and/or hearing specialists, and recommendations or referrals for environmental modifications. However, not all recommendations were consistently implemented; most commonly, adherence to recommendations was in the 60% to 70% range for any individual recommendation or referral. Additionally, several trials provided intervention components to all participants regardless of the results of the risk assessment. For example, 9 of 28 trials gave 100% of the intervention group participants an exercise intervention, while 17 trials referred patients as needed to an exercise intervention.4,11

A pooled analysis of 20 trials (n = 22,115) demonstrated that multifactorial interventions were associated with a significant reduction in the rate of incident falls at the longest follow-up (6–28 months) (IRR, 0.84 [95% CI, 0.74–0.95]). However, pooled analyses found no significant reductions in the number of persons experiencing a fall, injurious falls, fall-related fractures, or all-cause mortality.4,11

The USPSTF found evidence on other interventions, including environment assessment (6 trials), exercise in combination with education intervention (4 trials), medication review (4 trials), exercise in combination with environmental assessment (3 trials), psychological intervention (3 trials), and a group education intervention (1 trial).4,11 Studies of these other interventions were too few, too small, and had other limitations (eg, recommendations from an assessment were not always implemented) to allow the USPSTF to draw any definitive conclusions.

### Harms of Interventions

The USPSTF also reviewed the evidence on the harms of interventions to prevent falls. Half of the exercise trials reported harms, with generally minor musculoskeletal adverse effects being most common; serious harms were generally rare. Adverse events directly related to the exercise intervention were largely musculoskeletal discomfort and pain symptoms.3 One trial reported a fall-related wrist fracture,17 and another reported a hip fracture attributed to an exercise session.18

For trials studying multifactorial interventions, harms were sparsely reported. When reported, they were rare, minor, and associated with the exercise components of the multifactorial interventions. In total, 5 trials (n = 4199) reported harms associated with...
multifactorial interventions, such as falls without injuries, back pain, and musculoskeletal pain.4,11 Trials of other interventions reported harms sparsely or not at all, or in the intervention group but not in the control group.4,11

Response to Public Comment
A draft version of this recommendation statement was posted for public comment on the USPSTF website from December 5, 2023, to January 8, 2024. Some comments noted the need for risk assessment tools that have greater accuracy to identify persons at risk for falls. The USPSTF agrees and calls for research to develop and validate primary care–feasible risk assessment tools that accurately predict risk for falls in older adults in the Research Needs and Gaps table of this recommendation (Table 2). Some comments requested greater specificity about the types of exercise interventions that are recommended. In response, the USPSTF notes that the studies of exercise interventions it reviewed varied in several ways, such as providing individual vs group sessions and in the exercise components of the interventions. As noted in the recommendation statement, while it is difficult to identify specific components of exercise that are particularly effective, nearly all exercise interventions included gait, balance, and functional training, and most included a strength and resistance training component. Last, in response to public comment, the USPSTF clarified that its research gap on the effectiveness and harms of interventions in different functional groups includes groups at high risk of falls, such as persons 85 years or older.

Research Needs and Gaps
See Table 2 for research needs and gaps related to interventions for fall prevention in community-dwelling older adults.

Recommendations of Others
The CDC recommends STEADI, a coordinated approach for fall prevention in adults 65 years or older that consists of 3 core elements: screen to identify fall risk, assess modifiable risk factors, and intervene using effective clinical and community strategies to reduce the identified risk.19 The US Department of Health and Human Services recommends that older adults engage in multicomponent physical activity that includes balance training, as well as aerobic and muscle-strengthening activities, as part of the 150 to 300 minutes per week of moderate-intensity, or 75 to 150 minutes per week of vigorous-intensity aerobic physical activity recommended for all adults. The American Academy of Family Physicians supports the USPSTF 2018 recommendation on fall prevention in community-dwelling older adults.20

Affiliations of US Preventive Services Task Force (USPSTF) Members: George Washington University, Washington, DC (Nicholson); Brown University, Providence, Rhode Island (Silverstein); Tufts University School of Medicine, Boston, Massachusetts (Wong); Harvard Medical School, Boston, Massachusetts (Barry); Virginia Commonwealth University, Richmond (Chelmow); University of Washington, Seattle (Silverstein); University of Maryland School of Medicine, Baltimore (Davis); The University of Texas Health Science Center, San Antonio (Jaén, Tsevat); Tulane University, New Orleans, Louisiana (Krousel-Wood); University of California, San Francisco (Lee); University of Virginia, Charlottesville (Li); Case Western Reserve University, Cleveland, Ohio (Rao); University of Arizona, Tucson (Ruiz); University of Missouri, Columbia (Stevermer); University of Wisconsin, Milwaukee (Underwood); Indiana University, Bloomington (Wiehe).

Author Contributions: Dr Nicholson had full access to all of the data in the study and takes responsibility for the integrity of the data and the accuracy of the data analysis. The USPSTF members contributed equally to the recommendation statement.

Conflict of Interest Disclosures: Authors followed the policy regarding conflicts of interest described at https://uspreventiveservicestaskforce.org/uspstf/about-uspstf/conflict-interest-disclosures. All members of the USPSTF receive travel reimbursement and an honorarium for participating in USPSTF meetings. Dr Wong reported being an unpaid coauthor of several falls-related publications. Dr Lee reported receiving grant support from the National Institute on Aging (K24AG066998, R01AG079982). Dr Barry reported receiving grants from Healthwise, a nonprofit, outside the submitted work. No other disclosures were reported.

Funding/Support: The USPSTF is an independent, voluntary body. The US Congress mandates that the Agency for Healthcare Research and Quality (AHRQ) support the operations of the USPSTF.

Role of the Funder/Sponsor: AHRQ staff assisted in the following: development and review of the research plan, commission of the systematic evidence review from an Evidence-based Practice Center, coordination of expert review and public comment of the draft evidence report and draft recommendation statement, and the writing and preparation of the final recommendation statement and its submission for publication. AHRQ staff had no role in the approval of the final recommendation statement or the decision to submit for publication.

Disclaimer: Recommendations made by the USPSTF are independent of the US government. They should not be construed as an official position of AHRQ or the US Department of Health and Human Services.

Additional Contributions: We thank Howard Tracer, MD (AHRQ), who contributed to the writing of the manuscript, and Lisa Nicolella, MA (AHRQ), who assisted with coordination and editing.

Additional Information: Published by JAMA—Journal of the American Medical Association under arrangement with the Agency for Healthcare Research and Quality (AHRQ). ©2024 AMA and United States Government, as represented by the Secretary of the Department of Health and Human Services (HHS), by assignment from the members of the United States Preventive Services Task Force (USPSTF).
